

To our customers,

Old Company Name in Catalogs and Other Documents

On April 1st, 2010, NEC Electronics Corporation merged with Renesas Technology Corporation, and Renesas Electronics Corporation took over all the business of both companies. Therefore, although the old company name remains in this document, it is a valid Renesas Electronics document. We appreciate your understanding.

Renesas Electronics website: <http://www.renesas.com>

April 1st, 2010
Renesas Electronics Corporation

Issued by: Renesas Electronics Corporation (<http://www.renesas.com>)

Send any inquiries to <http://www.renesas.com/inquiry>.

Notice

1. All information included in this document is current as of the date this document is issued. Such information, however, is subject to change without any prior notice. Before purchasing or using any Renesas Electronics products listed herein, please confirm the latest product information with a Renesas Electronics sales office. Also, please pay regular and careful attention to additional and different information to be disclosed by Renesas Electronics such as that disclosed through our website.
2. Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
3. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part.
4. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.
5. When exporting the products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations. You should not use Renesas Electronics products or the technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations.
6. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.
7. Renesas Electronics products are classified according to the following three quality grades: “Standard”, “High Quality”, and “Specific”. The recommended applications for each Renesas Electronics product depends on the product’s quality grade, as indicated below. You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application categorized as “Specific” without the prior written consent of Renesas Electronics. Further, you may not use any Renesas Electronics product for any application for which it is not intended without the prior written consent of Renesas Electronics. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for an application categorized as “Specific” or for which the product is not intended where you have failed to obtain the prior written consent of Renesas Electronics. The quality grade of each Renesas Electronics product is “Standard” unless otherwise expressly specified in a Renesas Electronics data sheets or data books, etc.
 - “Standard”: Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots.
 - “High Quality”: Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti-crime systems; safety equipment; and medical equipment not specifically designed for life support.
 - “Specific”: Aircraft; aerospace equipment; submersible repeaters; nuclear reactor control systems; medical equipment or systems for life support (e.g. artificial life support devices or systems), surgical implantations, or healthcare intervention (e.g. excision, etc.), and any other applications or purposes that pose a direct threat to human life.
8. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.
9. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or system manufactured by you.
10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
11. This document may not be reproduced or duplicated, in any form, in whole or in part, without prior written consent of Renesas Electronics.
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.

(Note 1) “Renesas Electronics” as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.

(Note 2) “Renesas Electronics product(s)” means any product developed or manufactured by or for Renesas Electronics.

M32C/80 Group

Hardware Manual

RENESAS 16/32-BIT SINGLE-CHIP
MICROCOMPUTER
M16C FAMILY / M32C/80 SERIES

All information contained in these materials, including products and product specifications, represents information on the product at the time of publication and is subject to change by Renesas Electronics Corp. without notice. Please review the latest information published by Renesas Electronics Corp. through various means, including the Renesas Electronics Corp. website (<http://www.renesas.com>).

Keep safety first in your circuit designs!

1. Renesas Technology Corp. puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage. Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of non-flammable material or (iii) prevention against any malfunction or mishap.

Notes regarding these materials

1. These materials are intended as a reference to assist our customers in the selection of the Renesas Technology Corp. product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Renesas Technology Corp. or a third party.
2. Renesas Technology Corp. assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
3. All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Renesas Technology Corp. without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor for the latest product information before purchasing a product listed herein. The information described here may contain technical inaccuracies or typographical errors. Renesas Technology Corp. assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors. Please also pay attention to information published by Renesas Technology Corp. by various means, including the Renesas Technology Corp. Semiconductor home page (<http://www.renesas.com>).
4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corp. assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
5. Renesas Technology Corp. semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
6. The prior written approval of Renesas Technology Corp. is necessary to reprint or reproduce in whole or in part these materials.
7. If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination. Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
8. Please contact Renesas Technology Corp. for further details on these materials or the products contained therein.

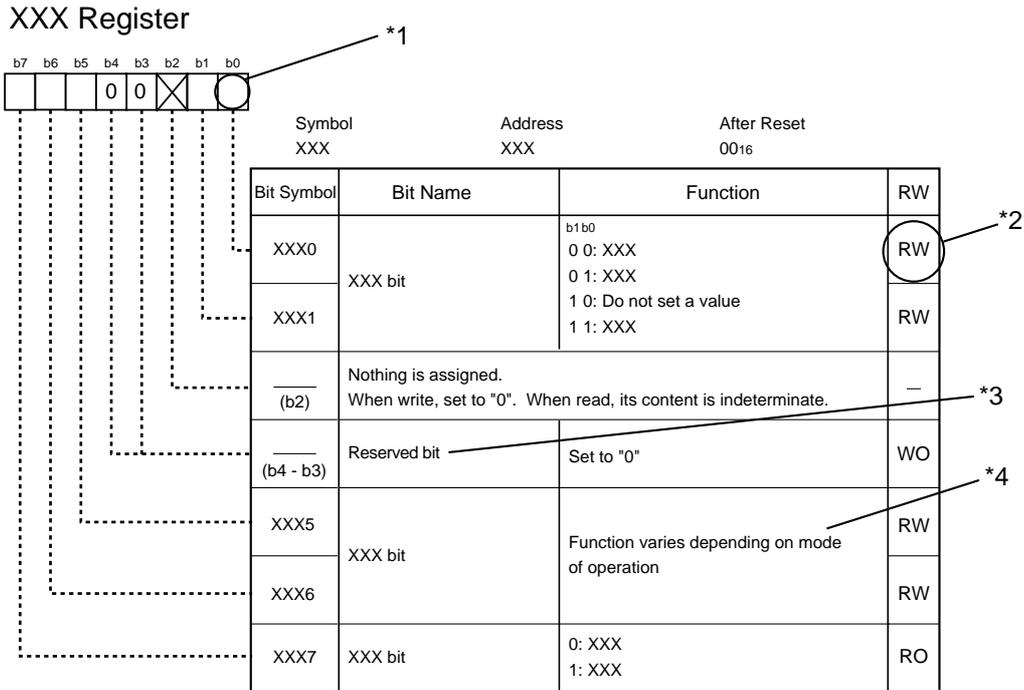

How to Use This Manual

1. Introduction

This hardware manual provides detailed information on the M32C/80 Group microcomputers. Users are expected to have basic knowledge of electric circuits, logical circuits and microcomputers.

2. Register Diagram

The symbols, and descriptions, used for bit function in each register are shown below.

*1
Blank: Set to "0" or "1" according to the application

- 0: Set to "0"
- 1: Set to "1"
- X: Nothing is assigned

*2
RW: Read and write
RO: Read only
WO: Write only
—: Nothing is assigned

*3
• Reserved bit
Reserved bit. Set to specified value.

*4
• Nothing is assigned
Nothing is assigned to the bit concerned. As the bit may be use for future functions, set to "0" when writing to this bit.

- Do not set a value
The operation is not guaranteed when a value is set.
- Function varies depending on mode of operation
Bit function varies depending on peripheral function mode.
Refer to respective register for each mode.

3. M16C Family Documents

The following documents were prepared for the M16C family. ⁽¹⁾

Document	Contents
Short Sheet	Hardware overview
Data Sheet	Hardware overview and electrical characteristics
Hardware Manual	Hardware specifications (pin assignments, memory maps, peripheral specifications, electrical characteristics, timing charts)
Software Manual	Detailed description of assembly instructions and microcomputer performance of each instruction
Application Note	<ul style="list-style-type: none">• Application examples of peripheral functions• Sample programs• Introduction to the basic functions in the M16C family• Programming method with Assembly and C languages
RENESAS TECHNICAL UPDATE	Preliminary report about the specification of a product, a document, etc.

NOTES :

1. Before using this material, please visit the our website to verify that this is the most current document available.

Table of Contents

Quick Reference by Address	B-1
1. Overview	1
1.1 Applications	1
1.2 Performance Overview	2
1.3 Block Diagram	3
1.4 Product Information	4
1.5 Pin Assignment	5
1.6 Pin Description	9
2. Central Processing Unit (CPU)	12
2.1 General Registers	13
2.1.1 Data Registers (R0, R1, R2 and R3).....	13
2.1.2 Address Registers (A0 and A1)	13
2.1.3 Static Base Register (SB).....	13
2.1.4 Frame Base Register (FB)	13
2.1.5 Program Counter (PC)	13
2.1.6 Interrupt Table Register (INTB)	13
2.1.7 User Stack Pointer (USP), Interrupt Stack Pointer (ISP)	13
2.1.8 Flag Register (FLG).....	13
2.2 High-Speed Interrupt Registers	14
2.3 DMAC-Associated Registers	14
3. Memory	15
4. Special Function Registers (SFRs)	16
5. Reset	30
5.1 Hardware Reset 1	30
5.1.1 Reset on a Stable Supply Voltage	30
5.1.2 Power-on Reset	30
5.2 Software Reset	33
5.3 Watchdog Timer Reset	33
5.4 Internal Space	33
6. Processor Mode	34
6.1 Types of Processor Mode.....	34
6.2 Setting of Processor Mode.....	35

7. Bus	39
7.1 Bus Settings	39
7.1.1 Selecting External Address Bus	40
7.1.2 Selecting External Data Bus	40
7.1.3 Selecting Separate/Multiplexed Bus	40
7.2 Bus Control	42
7.2.1 Address Bus and Data Bus	42
7.2.2 Chip-Select Signal	42
7.2.3 Read and Write Signals	44
7.2.4 Bus Timing	45
7.2.5 ALE Signal	53
7.2.6 $\overline{\text{RDY}}$ Signal	53
7.2.8 External Bus Status when Accessing Internal Space	55
7.2.7 $\overline{\text{HOLD}}$ Signal	55
7.2.9 BCLK Output	55
8. Clock Generation Circuit	56
8.1 Types of the Clock Generation Circuit	56
8.1.1 Main Clock	65
8.1.2 Sub Clock	66
8.1.3 On-Chip Oscillator Clock	67
8.1.4 PLL Clock	69
8.2 CPU Clock and BCLK	70
8.3 Peripheral Function Clock	70
8.3.1 f_1, f_8, f_{32} and f_{2n}	70
8.3.2 f_{AD}	70
8.3.3 f_{C32}	71
8.4 Clock Output Function	71
8.5 Power Consumption Control	72
8.5.1 Normal Operating Mode	72
8.5.2 Wait Mode	73
8.5.3 Stop Mode	75
8.6 System Clock Protect Function	80
9. Protection	81
10. Interrupts	82
10.1 Types of Interrupts	82

10.2	Software Interrupts	83
10.2.1	Undefined Instruction Interrupt	83
10.2.2	Overflow Interrupt	83
10.2.3	BRK Interrupt	83
10.2.4	BRK2 Interrupt	83
10.2.5	INT Instruction Interrupt	83
10.3	Hardware Interrupts	84
10.3.1	Special Interrupts	84
10.3.2	Peripheral Function Interrupt	84
10.4	High-Speed Interrupt	85
10.5	Interrupts and Interrupt Vectors	85
10.5.1	Fixed Vector Tables	86
10.5.2	Relocatable Vector Tables	86
10.6	Interrupt Request Acknowledgement	89
10.6.1	I Flag and IPL	89
10.6.2	Interrupt Control Register and RLVL Register	89
10.6.3	Interrupt Sequence	93
10.6.4	Interrupt Response Time	94
10.6.5	IPL Change when Interrupt Request is Acknowledged	95
10.6.6	Saving a Register	96
10.6.7	Restoration from Interrupt Routine	96
10.6.8	Interrupt Priority	97
10.6.9	Interrupt Priority Level Select Circuit	97
10.7	$\overline{\text{INT}}$ Interrupt	99
10.8	$\overline{\text{NMI}}$ Interrupt	100
10.9	Key Input Interrupt	100
10.10	Address Match Interrupt	101
10.11	Intelligent I/O Interrupt	102
11.	Watchdog Timer	105
11.1	Count Source Protection Mode	108
12.	DMAC	109
12.1	Transfer Cycle	116
12.1.1	Effect of Source and Destination Addresses	116
12.1.2	Effect of the DS Register	116
12.1.3	Effect of Software Wait State	116
12.1.4	Effect of $\overline{\text{RDY}}$ Signal	116
12.2	DMAC Transfer Cycle	118
12.3	Channel Priority and DMA Transfer Timing	118

13. DMAC II	120
13.1 DMAC II Settings	120
13.1.1 RLVL Register	120
13.1.2 DMAC II Index	122
13.1.3 Interrupt Control Register for the Peripheral Function	124
13.1.4 Relocatable Vector Table for the Peripheral Function	124
13.1.5 IRLT Bit in the IIOiE Register (i=0 to 4)	124
13.2 DMAC II Performance	124
13.3 Transfer Data	124
13.3.1 Memory-to-memory Transfer	124
13.3.2 Immediate Data Transfer	125
13.3.3 Calculation Transfer	125
13.4 Transfer Modes	125
13.4.1 Single Transfer	125
13.4.2 Burst Transfer	125
13.5 Multiple Transfer	125
13.6 Chained Transfer	126
13.7 End-of-Transfer Interrupt	126
13.8 Execution Time	127
14. Timer	128
14.1 Timer A	130
14.1.1 Timer Mode	136
14.1.2 Event Counter Mode	138
14.1.3 One-Shot Timer Mode	142
14.1.4 Pulse Width Modulation Mode	144
14.2 Timer B	147
14.2.1 Timer Mode	150
14.2.2 Event Counter Mode	151
14.2.3 Pulse Period/Pulse Width Measurement Mode	153
15. Three-Phase Motor Control Timer Functions	156
16. Serial I/O	167
16.1 Clock Synchronous Serial I/O Mode	177
16.1.1 Selecting CLK Polarity Selecting	181
16.1.2 Selecting LSB First or MSB First	181
16.1.3 Continuous Receive Mode	182
16.1.4 Serial Data Logic Inverse	182

16.2	Clock Asynchronous Serial I/O (UART) Mode	183
16.2.1	Bit Rate	187
16.2.2	Selecting LSB First or MSB First.....	188
16.2.3	Serial Data Logic Inverse	188
16.2.4	TxD and Rx D I/O Polarity Inverse	189
16.3	Special Mode 1 (I ² C Mode)	190
16.3.1	Detecting Start Condition and Stop Condition	196
16.3.2	Start Condition or Stop Condition Output.....	196
16.3.3	Arbitration	198
16.3.4	Transfer Clock	198
16.3.5	SDA Output.....	198
16.3.6	SDA Input.....	199
16.3.7	ACK, NACK.....	199
16.3.8	Transmit and Receive Reset	199
16.4	Special Mode 2	200
16.4.1	\overline{SS}_i Input Pin Function (i=0 to 4).....	203
16.4.2	Clock Phase Setting Function	204
16.5	Special Mode 3 (GCI Mode)	206
16.6	Special Mode 4 (IE Mode)	210
16.7	Special Mode 5 (SIM Mode)	214
16.7.1	Parity Error Signal	218
16.7.2	Format	219
17.	A/D Converter	220
17.1	Mode Description	227
17.1.1	One-shot Mode	227
17.1.2	Repeat Mode.....	228
17.1.3	Single Sweep Mode	229
17.1.4	Repeat Sweep Mode 0	230
17.1.5	Repeat Sweep Mode 1	231
17.2	Functions	232
17.2.1	Resolution Select Function.....	232
17.2.2	Sample and Hold Function.....	232
17.2.3	Trigger Select Function	232
17.2.4	DMAC Operating Mode	232
17.2.5	Extended Analog Input Pins	233
17.2.6	External Operating Amplifier (Op-Amp) Connection Mode.....	233
17.2.7	Power Consumption Reducing Function	234
17.2.8	Output Impedance of Sensor Equivalent Circuit under A/D Conversion ...	234

18. D/A Converter	236
19. CRC Calculation	239
20. X/Y Conversion	241
21. Intelligent I/O	244
21.1 Communication Unit 0 and 1 Communication Function	246
21.1.1 Clock Synchronous Serial I/O Mode (Communication Units 0 and 1)	256
21.1.2 HDLC Data Processing Mode (Communication Units 0 and 1)	259
22. Programmable I/O Ports	262
22.1 Port Pi Direction Register (PDi Register, i=0 to 10)	262
22.2 Port Pi Register (Pi Register, i=0 to 10)	262
22.3 Function Select Register Aj (PSj Register) (j=0 to 3)	262
22.4 Function Select Register B0 to B3 (PSL0 to PSL3 Registers)	262
22.5 Function Select Register C (PSC and PSC3 Registers)	263
22.6 Function Select Register D (PSD1 Register)	263
22.7 Pull-up Control Register 0 to 3 (PUR0 to PUR3 Registers)	263
22.8 Port Control Register (PCR Register)	263
22.9 Analog Input and Other Peripheral Function Input	263
23. Electrical Characteristics	281
24. Precautions	307
24.1 Reset	307
24.2 Bus	308

M32C/80 Group

SINGLE-CHIP 16/32-BIT CMOS MICROCOMPUTER

1. Overview

The M32C/80 Group microcomputer is a single-chip control unit that utilizes high-performance silicon gate CMOS technology with the M32C/80 series CPU core. The M32C/80 Group is available in 100-pin plastic molded LQFP/QFP package.

With a 16-Mbyte address space, this microcomputer combines advanced instruction manipulation capabilities to process complex instructions by less bytes and execute instructions at higher speed.

It incorporates a multiplier and DMAC adequate for office automation, communication devices and industrial equipments and other high-speed processing applications.

The M32C/80 Group is ROMless device.
Use the M32C/80 Group in microprocessor mode after reset.

1.1 Applications

Audio, cameras, office equipment, communications equipment, portable equipment, etc.

1.2 Performance Overview

Table 1.1 lists performance overview of the M32C/80 Group.

Table 1.1 M32C/80 Group Performance

Item		Performance
CPU	Basic Instructions	108 instructions
	Minimum Instruction Execution Time	31.3 ns (f(BCLK)=32 MHz, Vcc1=4.2 to 5.5 V) 41.7 ns (f(BCLK)=24 MHz, Vcc1=3.0 to 5.5 V)
	Operating Mode	Single-chip mode, Memory expansion mode, Microprocessor mode
	Memory Space	16 Mbytes
	Memory Capacity	See Table 1.2
Peripheral function	I/O Port	47 I/O pins (when using 16-bit bus) and 1 input pin
	Multifunction Timer	Timer A: 16 bits x 5 channels, Timer B: 16 bits x 6 channels Three-phase motor control circuit
	Intelligent I/O Communication Function	2 channels
	Serial I/O	5 channels Clock synchronous serial I/O, Clock asynchronous serial I/O, IEBus ⁽¹⁾ , I ² C Bus ⁽²⁾
	A/D Converter	10-bit A/D converter: 1 circuit, 10 channels
	D/A Converter	8 bits x 2 channels
	DMAC	4 channels
	DMAC II	Can be activated by all peripheral function interrupt sources Immediate transfer, operation and chain transfer function
	CRC Calculation Circuit	CRC-CCITT
	X/Y Converter	16 bits x 16 bits
	Watchdog Timer	15 bits x 1 channel (with prescaler)
	Interrupt	34 internal sources and 8 external sources, 5 software sources Interrupt priority level: 7
	Clock Generation Circuit	4 circuits Main Clock oscillation circuit (*), Sub clock oscillation circuit (*), On-chip oscillator, PLL frequency synthesizer (*)Equipped with a built-in feedback resistor
Oscillation Stop Detect Function	Main clock oscillation stop detect circuit	
Electrical Characteristics	Supply Voltage	Vcc1=4.2 to 5.5 V, Vcc2=3.0 to Vcc1 (f(BCLK)=32 MHz) Vcc1=3.0 to 5.5 V, Vcc2=3.0 to Vcc1 (f(BCLK)=24 MHz)
	Power Consumption	22 mA (Vcc1=Vcc2=5 V, f(BCLK)=32 MHz) 17 mA (Vcc1=Vcc2=3.3 V, f(BCLK)=24 MHz) 10 μA (Vcc1=Vcc2=3.3 V, f(BCLK)=32 kHz, in wait mode)
Operating Ambient Temperature		-20 to 85°C, -40 to 85°C(optional)
Package		100-pin plastic molded LQFP/QFP

NOTES:

1. IEBus is a trademark of NEC Electronics Corporation.
 2. I²C bus is a trademark of Koninklijke Philips Electronics N. V.
- All options are on a request basis.

1.3 Block Diagram

Figure 1.1 shows a block diagram of the M32C/80 Group microcomputer.

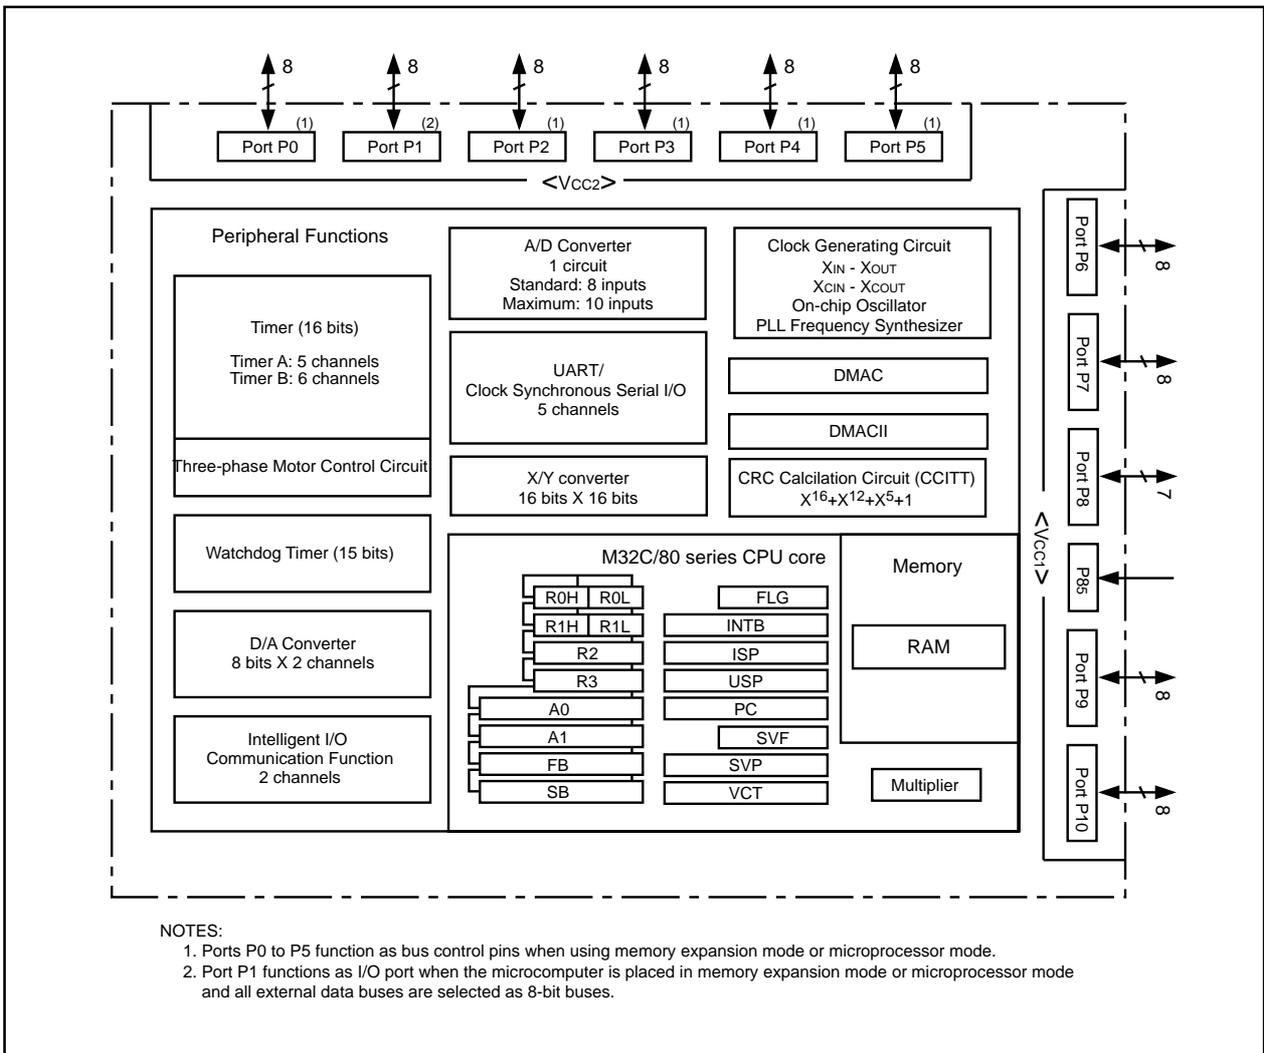

Figure 1.1 M32C/80 Group Block Diagram

1.4 Product Information

Table 1.2 lists the product information. Figure 1.2 shows the product numbering system.

Table 1.2 M32C/80 Group

As of November, 2005

Type Number	Package Type	ROM Capacity	RAM Capacity	Remarks
M30800SAGP	PLQP0100KB-A (100P6Q-A)	—	8K	ROMless
M30800SAFP	PRQP0100JB-A (100P6S-A)			
M30800SAGP-BL	PLQP0100KB-A (100P6Q-A)			ROMless with on-chip boot loader
M30800SAFP-BL	PRQP0100JB-A (100P6S-A)

1.6 Pin Description

Table 1.4 Pin Description

Signal name	Pin name	I/O type	Supply voltage	Description
Power supply	VCC1, VCC2 VSS	I	-	Apply 3.0 to 5.5 V to both VCC1 and VCC2 pins. Apply 0 V to the VSS pin. $VCC1 \geq VCC2^{(1)}$
Analog power supply input	AVCC AVSS	I	VCC1	Supplies power for the A/D converter. Connect the AVCC pin to VCC1 and the AVSS pin to VSS
Reset input	RESET	I	VCC1	The microcomputer is in a reset state when "L" is applied to the RESET pin
CNVss	CNVss	I	VCC1	Connect this pin to VCC1
External data bus width select input	BYTE	I	VCC1	Switches the data bus in external memory space 3. The data bus is 16 bits long when the this pin is held "L" and 8 bits long when the this pin is held "H". Set it to either one.
Bus control pins	D0 to D7	I/O	VCC2	Inputs and outputs data (D0 to D7) while accessing an external memory space with separate bus
	D8 to D15	I/O	VCC2	Inputs and outputs data (D8 to D15) while accessing an external memory space with 16-bit separate bus
	A0 to A22	O	VCC2	Outputs address bits (A0 to A22)
	A23	O	VCC2	Outputs inversed address bit A23
	A0/D0 to A7/D7	I/O	VCC2	Inputs and outputs data (D0 to D7) and outputs 8 low-order address bits (A0 to A7) by time-sharing while accessing an external memory space with multiplexed bus
	A8/D8 to A15/D15	I/O	VCC2	Inputs and outputs data (D8 to D15) and outputs 8 middle-order address bits (A8 to A15) by time-sharing while accessing an external memory space with multiplexed bus
	CS0 to CS3	O	VCC2	Output CS0 to CS3 that are chip-select signals specifying an external space
	WRL/WR WRH/BHE RD	O	VCC2	Outputs WRL, WRH, (WR, BHE) and RD signals. WRL and WRH can be switched with WR and BHE by program <ul style="list-style-type: none"> ■ WRL, WRH and RD are selected: If external data bus is 16 bits wide, data is writtenn to an even address when WRL is held "L". Data is written to an odd address when WRH is held "L". Data is read when RD is held "L". ■ WR, BHE and RD are selected Data is written to external memory space when WR is held "L". Data is read when RD is held "L". An odd address is accessed when BHE is held "L". Select WR, BHE and RD for an external 8-bit data bus
	ALE	O	VCC2	ALE is a signal latching address
	HOLD	I	VCC2	The microcomputer is placed in a hold state while the HOLD pin is held "L"
HLDA	O	VCC2	Outputs an "L" siganl while the microcomputer is placed in a hold state	
RDY	I	VCC2	Bus is placed in a wait state while the RDY pin is held "L"	

I: Input O: Output I/O: Input and output

NOTE:

1. In this manual, hereafter, VCC refers to VCC1 unless otherwise noted.

Table 1.4 Pin Description (Continued)

Signal name	Pin name	I/O type	Supply voltage	Description
Main clock input	XIN	I	VCC1	I/O pins for the main clock generation circuit. Connect a ceramic resonator or crystal oscillator between XIN and XOUT. To apply external clock, input the clock from XIN and leave XOUT open
Main clock output	XOUT	O	VCC1	
Sub clock input	XCIN	I	VCC1	I/O pins for a sub clock oscillation circuit. Connect a crystal oscillator between XCIN and XCOUT. To apply external clock, input the clock from XCIN and leave XCOUT open
Sub clock output	XCOUT	O	VCC1	
BCLK output	BCLK	O	VCC2	Outputs BCLK signal
Clock output	CLKOUT	O	VCC2	Outputs clock having the same frequency as f_c , f_8 , or f_{32}
INT interrupt input	INT0 to INT2	I	VCC1	Input pins for the $\overline{\text{INT}}$ interrupt
	INT3 to INT5		VCC2	
NMI interrupt input	NMI	I	VCC1	Input pin for the NMI interrupt
Key input interrupt	KI0 to KI3	I	VCC1	Input pins for the key input interrupt
Timer A	TA0OUT to TA4OUT	I/O	VCC1	I/O pins for the timer A0 to A4 (TA0OUT is a pin for the N-channel open drain output.)
	TA0IN to TA4IN		I	
Timer B	TB0IN to TB5IN	I	VCC1	Input pins for the timer B0 to B5
Three-phase motor control output	U, $\overline{\text{U}}$, V, $\overline{\text{V}}$, W, $\overline{\text{W}}$	O	VCC1	output pins for the three-phase motor control timer
Serial I/O	CTS0 to CTS4	I	VCC1	Input pins for data transmission control
	RTS0 to RTS4	O	VCC1	Output pins for data reception control
	CLK0 to CLK4	I/O	VCC1	Inputs and outputs the transfer clock
	RxD0 to RxD4	I	VCC1	Inputs serial data
	TxD0 to TxD4	O	VCC1	Outputs serial data (TxD2 is a pin for the N-channel open drain output.)
I ² C mode	SDA0 to SDA4	I/O	VCC1	Inputs and outputs serial data (SDA2 is a pin for the N-channel open drain output.)
	SCL0 to SCL4		VCC1	Inputs and outputs the transfer clock (SCL2 is a pin for the N-channel open drain output.)
Serial I/O special function	STxD0 to STxD4	I	VCC1	Outputs serial data when slave mode is selected (SDA2 is a pin for the N-channel open drain output.)
	SRxD0 to SRxD4	I	VCC1	Inputs serial data when slave mode is selected
	SS0 to SS4	I	VCC1	Input pins to control serial I/O special function

I: Input O: Output I/O: Input and output

Table 1.5 Pin Description (Continued)

Signal name	Pin name	I/O type	Supply voltage	Description			
Reference voltage input	VREF	I	-	Applies reference voltage for the A/D converter and D/A converter			
A/D converter	AN0 to AN7	I	VCC1	Analog input pins for the A/D converter			
	ADTRG	I	VCC1	Input pin for an external A/D trigger			
	ANEX0	I/O	VCC1	Extended analog input pin for the A/D converter and output pin in external op-amp connection mode			
	ANEX1	I	VCC1	Extended analog input pin for the A/D converter			
D/A converter	DA0, DA1	O	VCC1	Output pin for the D/A converter			
Intelligent I/O communication function	ISCLK0	I/O	VCC1	Inputs and outputs clock for the intelligent I/O communication function			
	ISCLK1						
	ISTxD0	O	VCC1	Outputs data for the intelligent I/O communication function			
	ISTxD1						
	ISRxD0	I	VCC1	Inputs data for the intelligent I/O communication function			
	ISRxD1						
I/O port	P00 to P07 ⁽¹⁾ P10 to P17 ⁽²⁾ P20 to P27 ⁽¹⁾ P30 to P37 ⁽¹⁾ P40 to P47 ⁽¹⁾ P50 to P57 ⁽¹⁾	I/O	VCC2	I/O ports fro CMOS. Each port can be programmed for nput or output under the control of the direction register. An input port can be set, by program, for a pull-up resistor available or for no pull-up resistor available in 4-bit units			
	P60 to P67 P70 to P77 P90 to P97 P100 to P107				I/O	VCC1	I/O ports having equivalent functions to P0 (P70 and P71 are ports for the N-channel open drain output.)
	P80 to P84, P86, P87						
	P85				I	VCC1	Shares a pin with NMI. NMI input state can be got by reading P85

I: Input O: Output I/O: Input and output

NOTES:

1. Ports P0 to P5 function as bus control pins when using memory expansion mode or microprocessor mode. They cannot be used as I/O ports.
2. Port P1 functions as I/O port when the microcomputer is placed in memory expansion mode or microprocessor mode and all external data buses are selected as 8-bit buses.

2. Central Processing Unit (CPU)

Figure 2.1 shows the CPU registers.

The register bank is comprised of 8 registers (R0, R1, R2, R3, A0, A1, SB and FB) out of 28 CPU registers. Two sets of register banks are provided.

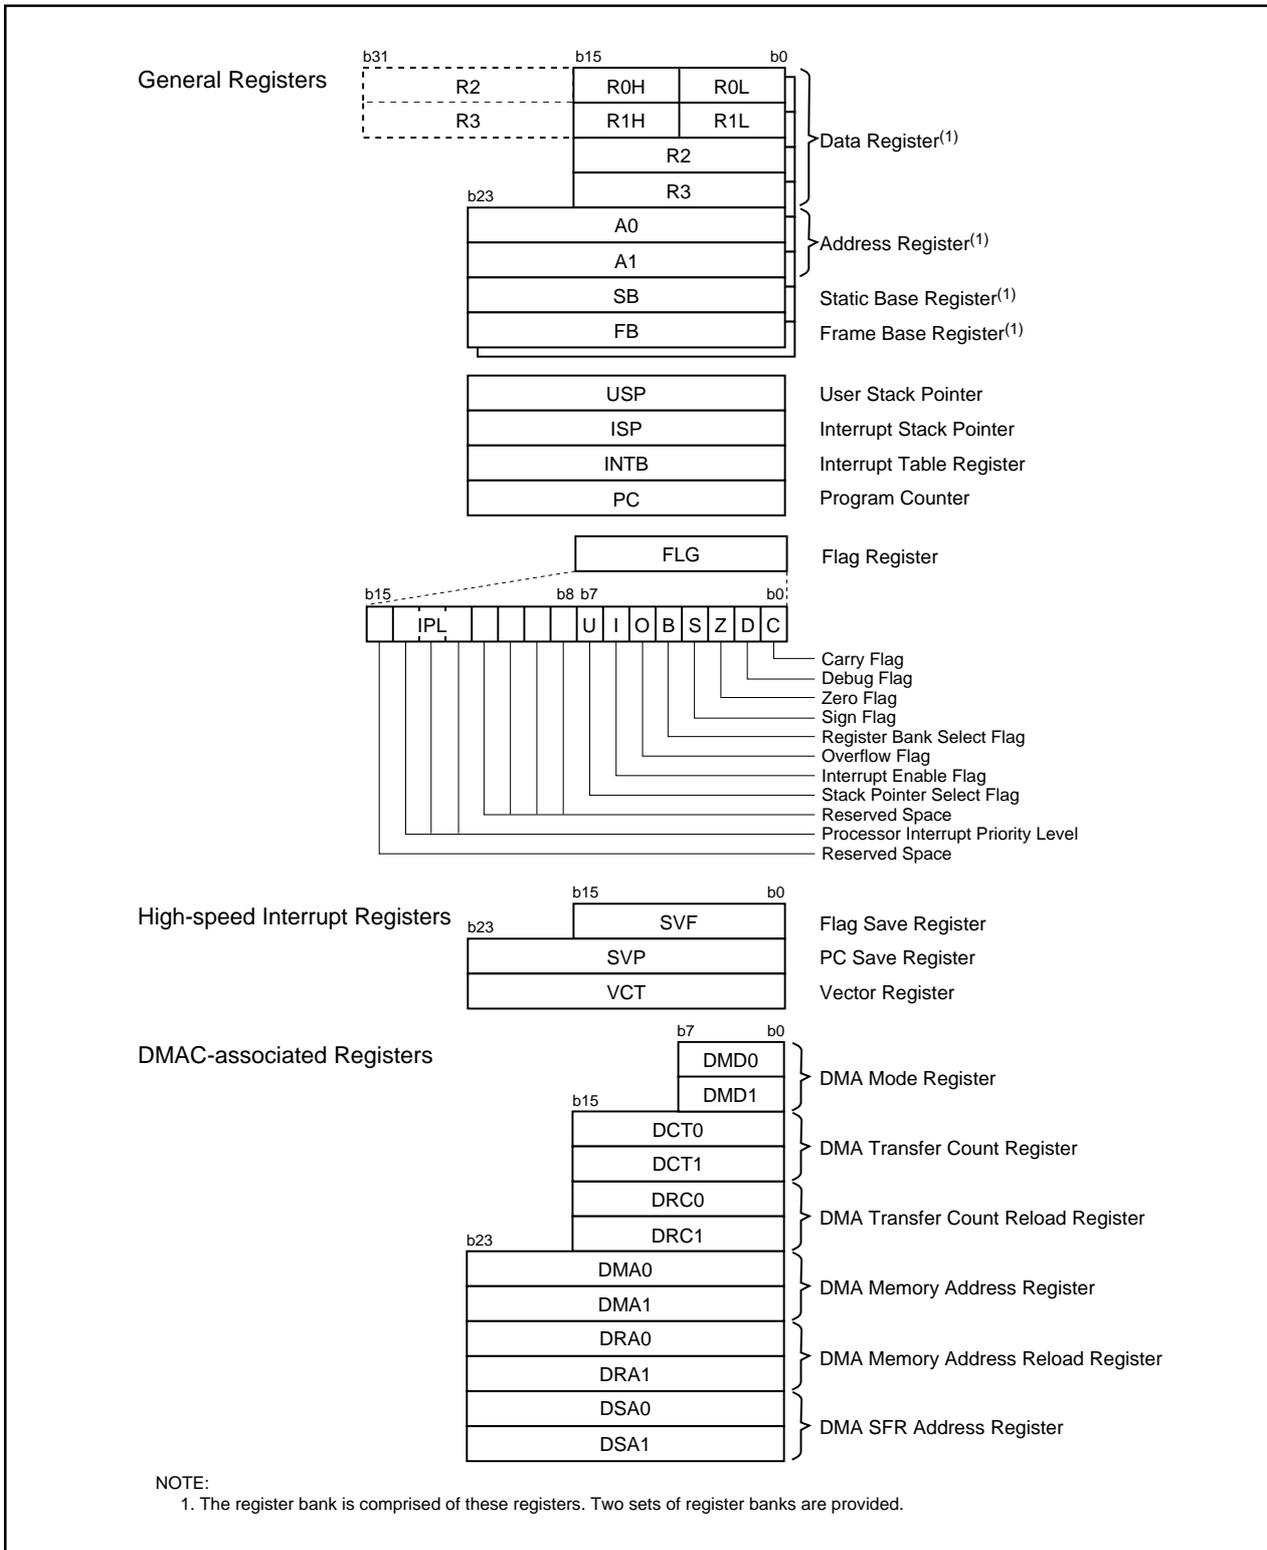

Figure 2.1 CPU Register

2.1 General Registers

2.1.1 Data Registers (R0, R1, R2 and R3)

R0, R1, R2 and R3 are 16-bit registers for transfer, arithmetic and logic operations. R0 and R1 can be split into high-order bits (R0H) and low-order bits (R0L) to be used separately as 8-bit data registers. R0 can be combined with R2 to be used as a 32-bit data register (R2R0). The same applies to R1 and R3.

2.1.2 Address Registers (A0 and A1)

A0 and A1 are 24-bit registers for A0-/A1-indirect addressing, A0-/A1-relative addressing, transfer, arithmetic and logic operations.

2.1.3 Static Base Register (SB)

SB is a 24-bit register for SB-relative addressing.

2.1.4 Frame Base Register (FB)

FB is a 24-bit register for FB-relative addressing.

2.1.5 Program Counter (PC)

PC, 24 bits wide, indicates the address of an instruction to be executed.

2.1.6 Interrupt Table Register (INTB)

INTB is a 24-bit register indicating the starting address of an relocatable interrupt vector table.

2.1.7 User Stack Pointer (USP), Interrupt Stack Pointer (ISP)

The stack pointers (SP), USP and ISP, are 24 bits wide each. The U flag is used to switch between USP and ISP. Refer to **2.1.8 Flag Register (FLG)** for details on the U flag. Set USP and ISP to even addresses to execute an interrupt sequence efficiently.

2.1.8 Flag Register (FLG)

FLG is a 16-bit register indicating a CPU state.

2.1.8.1 Carry Flag (C)

The C flag indicates whether carry or borrow has occurred after executing an instruction.

2.1.8.2 Debug Flag (D)

The D flag is for debug only. Set to "0".

2.1.8.3 Zero Flag (Z)

The Z flag is set to "1" when the value of zero is obtained from an arithmetic operation; otherwise "0".

2.1.8.4 Sign Flag (S)

The S flag is set to "1" when a negative value is obtained from an arithmetic operation; otherwise "0".

2.1.8.5 Register Bank Select Flag (B)

The register bank 0 is selected when the B flag is set to "0". The register bank 1 is selected when this flag is set to "1".

2.1.8.6 Overflow Flag (O)

The O flag is set to "1" when the result of an arithmetic operation overflows; otherwise "0".

2.1.8.7 Interrupt Enable Flag (I)

The I flag enables a maskable interrupt.

Interrupt is disabled when the I flag is set to "0" and enabled when the I flag is set to "1". The I flag is set to "0" when an interrupt is acknowledged.

2.1.8.8 Stack Pointer Select Flag (U)

ISP is selected when the U flag is set to "0". USP is selected when this flag is set to "1".

The U flag is set to "0" when a hardware interrupt is acknowledged or the INT instruction of software interrupt numbers 0 to 31 is executed.

2.1.8.9 Processor Interrupt Priority Level (IPL)

IPL, 3 bits wide, assigns processor interrupt priority levels from level 0 to level 7.

If a requested interrupt has greater priority than IPL, the interrupt is enabled.

2.1.8.10 Reserved Space

When writing to a reserved space, set to "0". When reading, its content is indeterminate.

2.2 High-Speed Interrupt Registers

Registers associated with the high-speed interrupt are as follows:

- Flag save register (SVF)
- PC save register (SVP)
- Vector register (VCT)

Refer to **10.4 High-Speed Interrupt** for details.

2.3 DMAC-Associated Registers

Registers associated with DMAC are as follows:

- DMA mode register (DMD0, DMD1)
- DMA transfer count register (DCT0, DCT1)
- DMA transfer count reload register (DRC0, DRC1)
- DMA memory address register (DMA0, DMA1)
- DMA SFR address register (DSA0, DSA1)
- DMA memory address reload register (DRA0, DRA1)

Refer to **12. DMAC** for details.

3. Memory

Figure 3.1 shows a memory map of the M32C/80 Group.

The M32C/80 Group provides 16-Mbyte address space addressed from 000000₁₆ to FFFFFFF₁₆.

The fixed interrupt vectors are allocated from address FFFFDC₁₆ to FFFFFFF₁₆. It stores the starting address of each interrupt routine.

The internal RAM is allocated from address 000400₁₆ to higher. For example, a 8-Kbyte internal RAM is allocated from address 000400₁₆ to 0023FF₁₆. Besides storing data, it becomes stacks when the subroutine is called or an interrupt is acknowledged.

SFRs, consisting of control registers for peripheral functions such as I/O port, A/D converter, serial I/O, timers, is allocated from address 000000₁₆ to 0003FF₁₆. All blank spaces within SFRs are reserved and cannot be accessed by users.

The special page vector table is addressed from FFFE00₁₆ to FFFFDB₁₆. It is used for the JMPS instruction and JSRS instruction. Refer to the Renesas publication **M32C/80 Series Software Manual** for details. In microprocessor mode, some spaces are reserved and cannot be accessed by users.

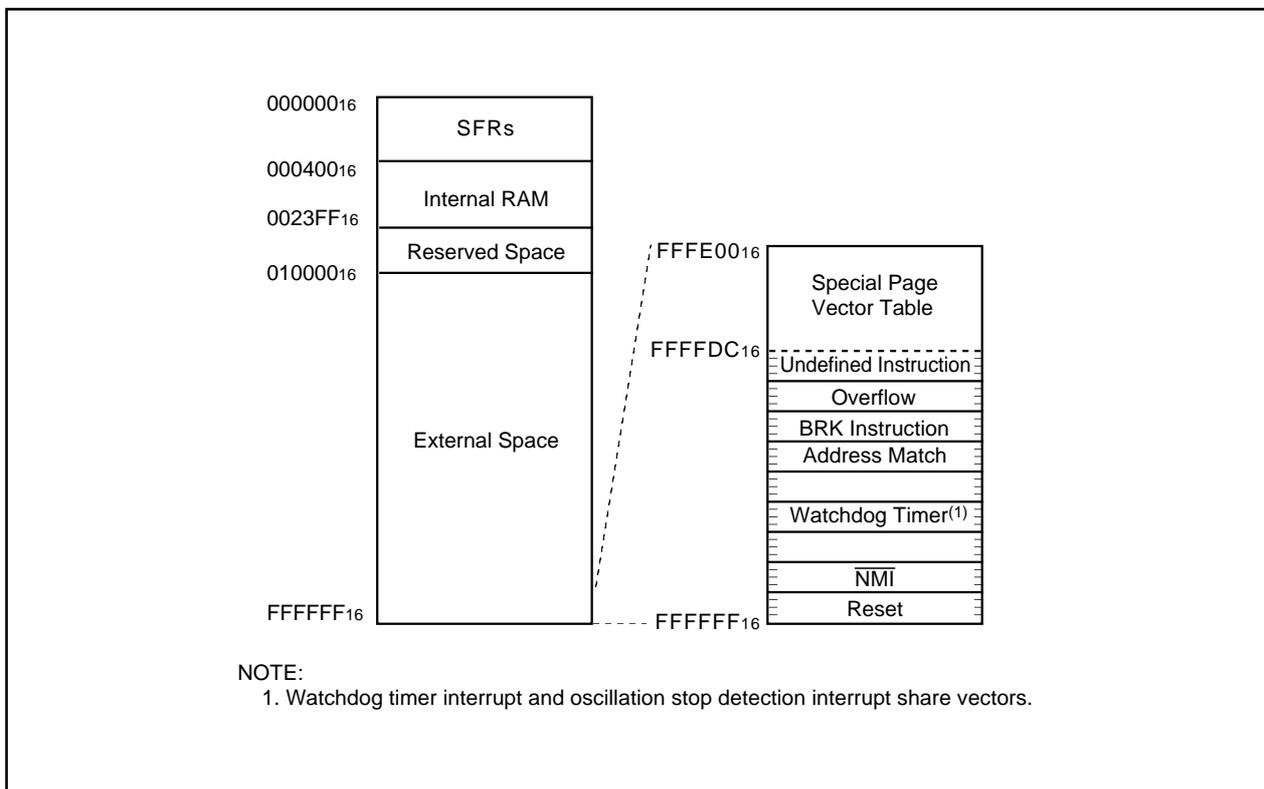

Figure 3.1 Memory Map

4. Special Function Registers (SFRs)

X: Indeterminate

Blank spaces are reserved. No access is allowed.

NOTE:

1. Pins, functioning as bus control pins, cannot be selected as I/O ports.

5. Reset

Hardware reset 1, software reset, and watchdog timer reset are available to reset the microcomputer.

5.1 Hardware Reset 1

Pins, the CPU and SFRs are reset by setting the $\overline{\text{RESET}}$ pin. If the supply voltage meets the recommended operating conditions, all pins are reset when a low-level ("L") signal is applied to the $\overline{\text{RESET}}$ pin (see **Table 5.1**). The oscillation circuit is also reset and the main clock starts oscillating. The CPU and SFR are reset when the signal applied to the $\overline{\text{RESET}}$ pin changes "L" to high level ("H"). The microcomputer executes the program in an address indicated by the reset vector. The internal RAM is not reset. When an "L" signal is applied to the $\overline{\text{RESET}}$ pin while writing data to the internal RAM, the internal RAM is in an indeterminate state.

Figure 5.1 shows an example of the reset circuit. Figure 5.2 shows a reset sequence. Table 5.1 lists pin states while the $\overline{\text{RESET}}$ pin is held "L".

5.1.1 Reset on a Stable Supply Voltage

- (1) Apply an "L" signal to the $\overline{\text{RESET}}$ pin
- (2) Provide 20 or more clock cycle inputs into the XIN pin
- (3) Apply an "H" signal to the $\overline{\text{RESET}}$ pin

5.1.2 Power-on Reset

- (1) Apply an "L" signal to the $\overline{\text{RESET}}$ pin
- (2) Raise the supply voltage to the recommended operating level
- (3) Insert $td(P-R)$ ms as wait time for the internal voltage to stabilize
- (4) Provide 20 or more clock cycle inputs into the XIN pin
- (5) Apply an "H" signal to the $\overline{\text{RESET}}$ pin

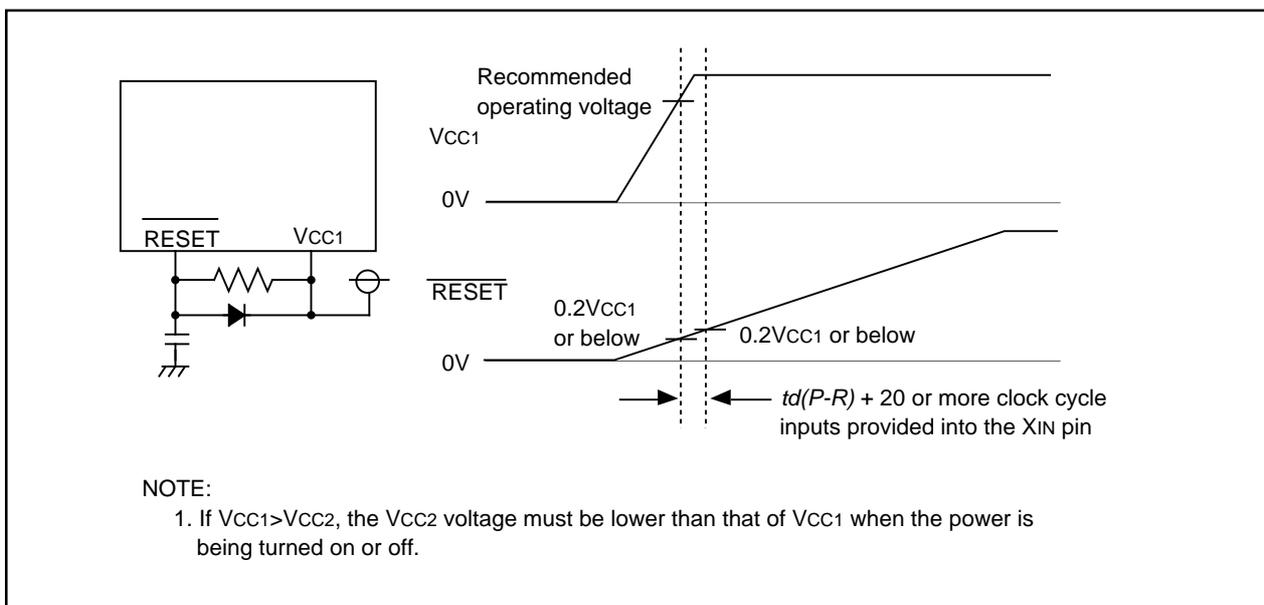

Figure 5.1 Reset Circuit

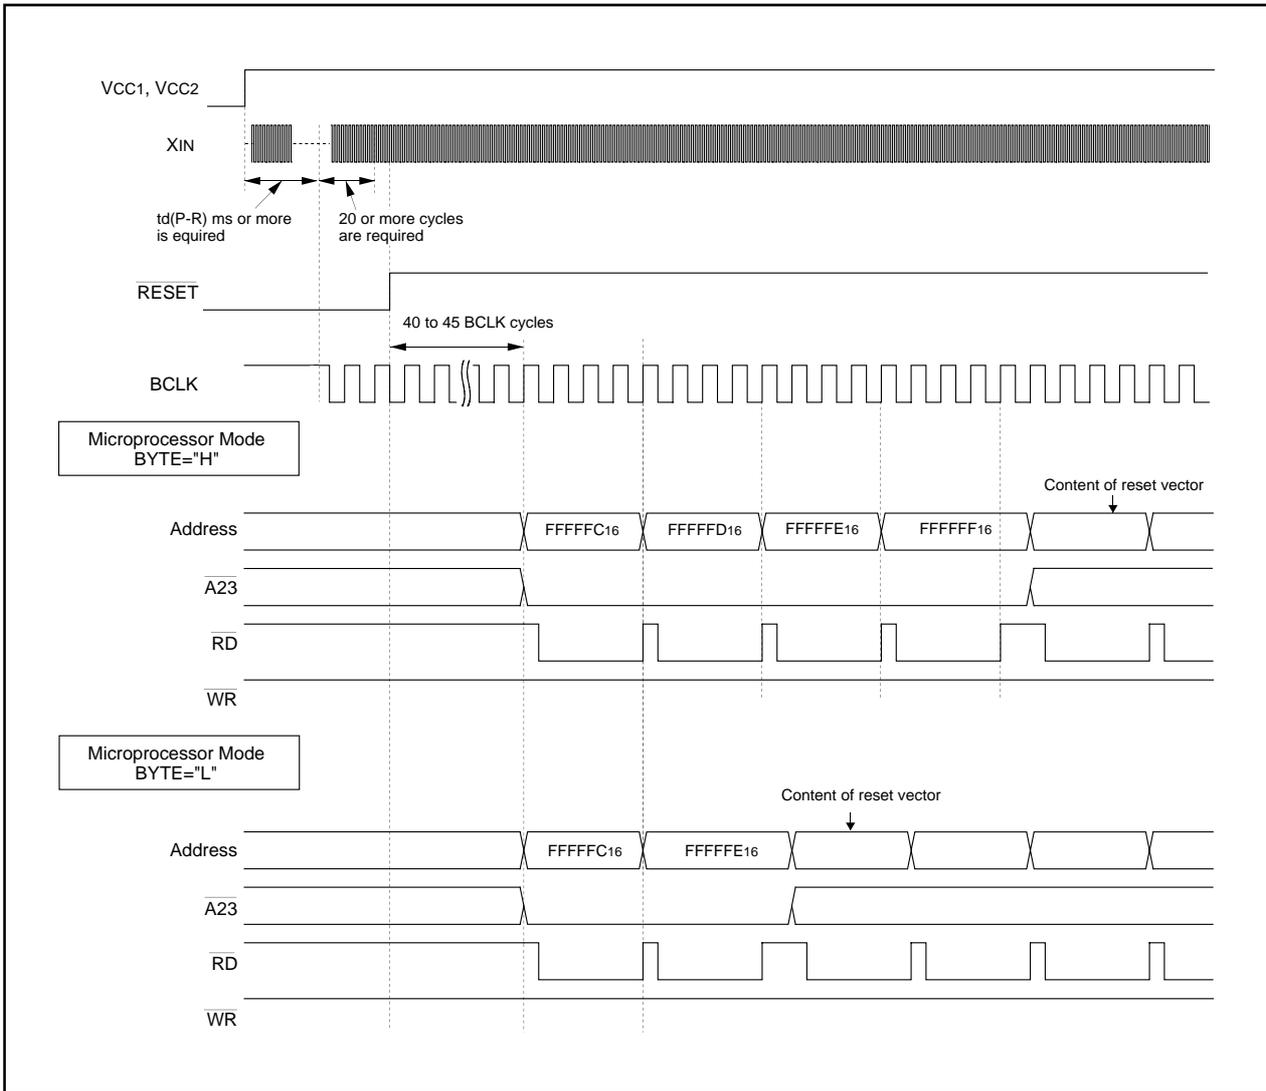

Figure 5.2 Reset Sequence

Table 5.1 Pin States while $\overline{\text{RESET}}$ Pin is Held "L"

Pin Name	Pin States ⁽¹⁾		
	CNVss=Vss	CNVss=Vcc	
		BYTE=Vss	BYTE=Vcc
P0	Input port (high-impedance)	Inputs data (high-impedance)	
P1	Input port (high-impedance)	Inputs data (high-impedance)	Input port (high-impedance)
P2, P3, P4	Input port (high-impedance)	Output addresses (indeterminate)	
P50	Input port (high-impedance)	Outputs the $\overline{\text{WR}}$ signal ("H") ⁽²⁾	
P51	Input port (high-impedance)	Outputs the $\overline{\text{BHE}}$ signal (indeterminate)	
P52	Input port (high-impedance)	Outputs the $\overline{\text{RD}}$ signal ("H") ⁽²⁾	
P53	Input port (high-impedance)	Outputs the BCLK ⁽²⁾	
P54	Input port (high-impedance)	Outputs the $\overline{\text{HLDA}}$ signal (Output signal depends on an input signal to the $\overline{\text{HOLD}}$ pin) ⁽²⁾	
P55	Input port (high-impedance)	Inputs the HOLD signal (high-impedance)	
P56	Input port (high-impedance)	Outputs an "H" signal ⁽²⁾	
P57	Input port (high-impedance)	Inputs the RDY signal (high-impedance)	
P6 to P10	Input port (high-impedance)	Input port (high-impedance)	

NOTES:

1. The availability of pull-up resistors is indeterminate until internal supply voltage stabilizes.
2. Each port is in this state after power is on and internal supply voltage stabilizes, but in an indeterminate state until internal supply voltage stabilizes.

5.2 Software Reset

Pins, the CPU and SFRs are reset when the PM03 bit in the PM0 register is set to "1" (microcomputer reset). Then the microcomputer executes the program in an address determined by the reset vector. Set the PM03 bit to "1" while the main clock is selected as the CPU clock and the main clock oscillation is stable.

In the software reset, the microcomputer does not reset a part of SFR. Refer to **4. Special Function Registers (SFRs)** for details. Processor mode remains unchanged since the PM01 and PM00 bits in the PM0 register are not reset.

5.3 Watchdog Timer Reset

Pins, the CPU and SFRs are reset when the CM06 bit in the CM0 register is set to "1" (reset) and the watchdog timer underflows. Then the microcomputer executes the program in an address determined by the reset vector.

In the watchdog timer reset, the microcomputer does not reset a part of the SFR. Refer to **4. Special Function Registers (SFRs)** for details. Processor mode remains unchanged since the PM01 and PM00 bits in the PM0 register are not reset.

5.4 Internal Space

Figure 5.3 shows CPU register states after reset. Refer to **4. Special Function Registers (SFRs)** for SFR states after reset.

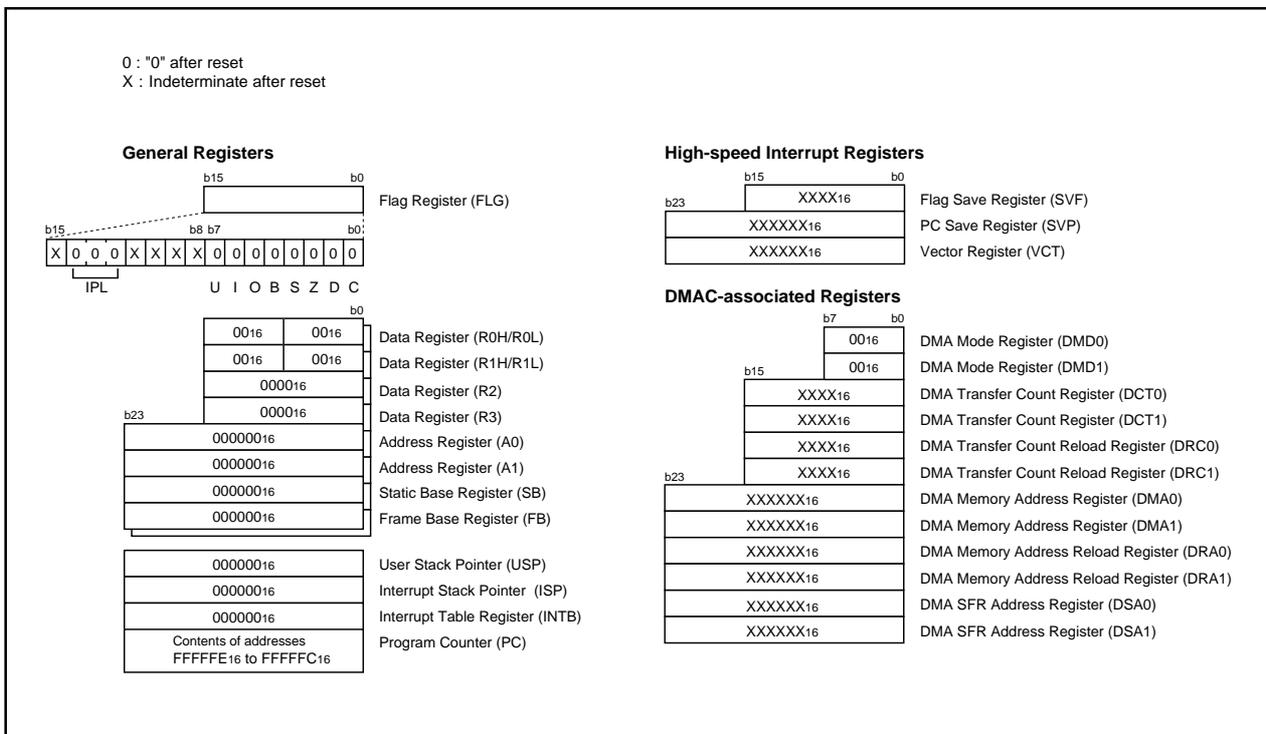

Figure 5.3 CPU Register States after Reset

6. Processor Mode

NOTE

The M32C/80 Group is ROMless device. Connect the CNVss pin to VCC1.
Use the M32C/80 Group in microprocessor mode after reset.

6.1 Types of Processor Mode

Single-chip mode, memory expansion mode, or microprocessor mode can be selected as a processor mode. Table 6.1 lists a feature of the processor mode.

Table 6.1 Processor Mode Feature

Processor Mode	Accessable Space	Pin Status as I/O Ports
Single-chip Mode	SFRs, Internal RAM	All pins assigned to I/O ports or to I/O pins for the peripheral functions
Memory Expansion Mode	SFRs, Internal RAM, External Space ⁽¹⁾	Some pins assigned to bus control pins ⁽¹⁾
Microprocessor Mode	SFRs, Internal RAM, External Space ⁽¹⁾	Some pins assigned to bus control pins ⁽¹⁾

NOTE:

1. Refer to **7. Bus** for details.

6.2 Setting of Processor Mode

The CNVss pin state and the PM01 and PM00 bit settings in the PM0 register determine which processor mode is selected. Table 6.2 lists processor mode after hardware reset. Table 6.3 lists processor mode selected by PM01 and PM00 bit settings.

Table 6.2 Processor Mode after Hardware Reset

Input Level into the CNVss pin	Processor Mode
Vcc1 ⁽¹⁾	Microprocessor Mode

NOTE:

1. Multiplex bus cannot be assigned to all \overline{CS} areas.

Table 6.3 Processor Mode Selected by the PM01 and PM00 bit Settings

PM01 and PM00 Bits	Processor Mode
002	Single-chip Mode
012	Memory Expansion Mode
102	Do not set to this value
112	Microprocessor Mode

If the PM01 and PM00 bits are rewritten, the PM01 and PM00 bits select a mode regardless of CNVss pin level.

Do not change the PM01 and PM00 bits to "012" (memory expansion mode) or "112" (microprocessor mode) when the PM07 to PM02 bits in the PM0 register are being rewritten.

Figures 6.1 and 6.2 show the PM0 register and PM1 register. Figure 6.3 shows a memory map in each processor mode.

Figure 6.3 Memory Map in Each Processor Mode

7. Bus

In memory expansion mode or microprocessor mode, some pins function as bus control pins to control the address bus and data bus. A₀ to A₂₂, \overline{A}_{23} , D₀ to D₁₅, CS₀ to CS₃, WRL/WR, WRH/BHE, RD, BCLK/ALE, $\overline{HLDA/ALE}$, \overline{HOLD} , ALE, \overline{RDY} are used as bus control pins.

7.1 Bus Settings

The BYTE pin, the DS register, the PM05 and PM04 bits in the PM0 register, and the PM11 and PM10 bits in the PM1 register determine bus settings.

Table 7.1 lists how to change bus settings. Figure 7.1 shows the DS register.

Table 7.1 Bus Settings

Bus Setting	Changed By
Selecting External Address Bus Width	DS register
Setting Bus Width after Reset	BYTE pin (external space 3 only)
Selecting Between Separate Bus or Multiplexed Bus	PM05 and PM04 bits in PM0 register
Number of Chip-select	PM11 and PM10 bits in PM1 register

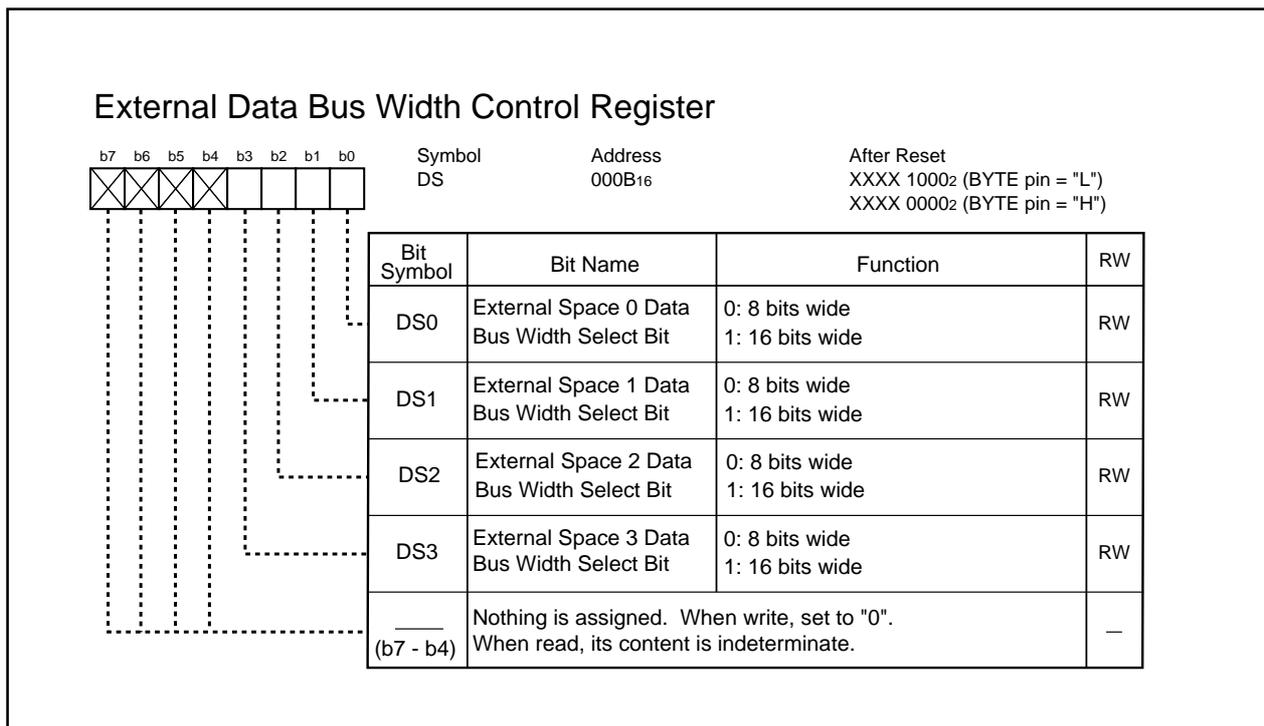

Figure 7.1 DS Register

7.1.1 Selecting External Address Bus

The number of externally-output address buses, the number of chip-select signals and chip-select-assigned address space (\overline{CS} area) vary depending on each external space mode. The PM11 and PM10 bits in the PM1 register determine the external space mode.

7.1.2 Selecting External Data Bus

The DS register selects either external 8-bit or 16-bit data bus per external space. The data bus in the external space 3, after reset, becomes 16 bits wide when a low-level ("L") signal is applied to the BYTE pin and 8 bits wide when a high-level ("H") signal is applied. Keep the BYTE pin input level while the microcomputer is operating. Internal bus is always 16 bits wide.

7.1.3 Selecting Separate/Multiplexed Bus

The PM05 and PM04 bits in the PM0 register determine either separate or multiplexed bus as bus format.

7.1.3.1 Separate Bus

The separate bus is a bus format which allows the microcomputer to input and output data and address separately. The DS register selects 8-bit or 16-bit data bus as the external data bus per external space. If all DS_i bits in the DS register (i=0 to 3) are set to "0" (8-bit data bus), port P0 becomes the data bus and port P1, the programmable I/O port. If one of the DS_i bits is set to "1" (16-bit data bus), ports P0 and P1 become the data bus. Port P1 is indeterminate when the microcomputer accesses a space where the DS_i bit is set to "0".

The EWCR_i register (i=0 to 3) determines the number of software wait states inserted, when the microcomputer accesses space using the separate bus.

7.1.3.2 Multiplexed Bus

The multiplexed bus is a bus format which allow the microcomputer to input and output data and address by timesharing. D₀ to D₇ are multiplexed with A₀ to A₇ in space accessed by the 8-bit data bus. D₀ to D₁₅ are multiplexed with A₀ to A₁₅ in space accessed by the 16-bit data bus. The DS_i bit controls the data bus width. The EWCR_i register (i=0 to 3) controls the number of software wait states inserted, when the microcomputer accesses a space using the multiplexed bus. Refer to **7.2.4 Bus Timing** for details.

The multiplexed bus can be assigned to access the $\overline{CS1}$ area, $\overline{CS2}$ area or all \overline{CS} areas. However, because the microcomputer starts operation using the separate bus after reset, the multiplexed bus cannot be assigned to access all \overline{CS} areas in microprocessor mode. When the PM05 and PM04 bits in the PM0 register are set to "112" (access all \overline{CS} areas with the bus), 16 low-order bits, from A₀ to A₁₅, of an address are output. See **Table 7.2** for details.

Table 7.2 Processor Mode and Port Function

Processor Mode	Single-Chip Mode	Memory Expansion Mode/ Microprocessor Mode				Memory Expansion Mode	
PM05 to PM04 Bits in PM0 Register		"012", "102" (Access $\overline{CS1}$ or $\overline{CS2}$ using the Multiplexed Bus Access All Other \overline{CS} Areas using the Separate Bus)		"002" (Access all \overline{CS} Areas using the Separate Bus)		"112" ⁽¹⁾ (Access all \overline{CS} Areas using the Multiplexed Bus)	
Data Bus Width		Access all external space with 8-bit data bus	Access one or more external space with 16-bit data bus	Access all external space with 8-bit data bus	Access one or more external space with 16-bit data bus	Access all external space with 8-bit data bus	Access one or more external space with 16-bit data bus

P44 to P46	I/O port	\overline{CS} (Chip-select signal) or Address bus (A20 to A22) (Refer to 7.2 Bus Control for details) ⁽⁴⁾					
P47	I/O port	\overline{CS} (Chip-select signal) or Address bus (A23) (Refer to 7.2 Bus Control for details) ⁽⁴⁾					
P50 to P53	I/O port	Outputs \overline{RD} , \overline{WRL} , \overline{WRH} and \overline{BCLK} or outputs \overline{RD} , \overline{BHE} , \overline{WR} and \overline{BCLK} (Refer to 7.2 Bus Control for details) ⁽³⁾					
P54	I/O port	\overline{HDLA} ⁽³⁾	\overline{HDLA} ⁽³⁾	\overline{HDLA} ⁽³⁾	\overline{HDLA} ⁽³⁾	\overline{HDLA} ⁽³⁾	\overline{HDLA} ⁽³⁾
P55	I/O port	\overline{HOLD}	\overline{HOLD}	\overline{HOLD}	\overline{HOLD}	\overline{HOLD}	\overline{HOLD}
P56	I/O port	ALE ⁽³⁾	ALE ⁽³⁾	ALE ⁽³⁾	ALE ⁽³⁾	ALE ⁽³⁾	ALE ⁽³⁾
P57	I/O port	\overline{RDY}	\overline{RDY}	\overline{RDY}	\overline{RDY}	\overline{RDY}	\overline{RDY}

NOTES:

- The PM05 and PM04 bits cannot be set to "112" (access all \overline{CS} areas using multiplexed bus) in microprocessor mode because the microcomputer starts operation using the separate bus after reset.
When the PM05 and PM04 bits are set to "112" in memory expansion mode, the microcomputer accesses 64-Kbyte memory space per chip-select using the address bus.
- These ports become address buses when accessing space using the separate bus.
- The PM15 and PM14 bits in the PM1 register determines which pin outputs the ALE signal. The PM02 bit in the PM0 register selects either " \overline{WRL} , \overline{WRH} " or " \overline{BHE} , \overline{WR} " combination.
P56 provides an indeterminate output when the PM15 and PM14 bits to "002" (no ALE). It cannot be used as an I/O port.
- The PM11 and PM10 bits in the PM1 register determine the \overline{CS} signal and address bus.

7.2 Bus Control

Signals, required to access external devices, are provided and software wait states are inserted as follows. The signals are available in memory expansion mode and microprocessor mode only.

7.2.1 Address Bus and Data Bus

Address bus is a signal accessing 16-Mbyte space and uses 24 control pins; A0 to A22 and $\overline{A23}$. $\overline{A23}$ is the inversed output signal of the highest-order address bit.

Data bus is a signal for data input and output. The DS register selects an 8-bit data bus from D0 to D7 or a 16-bit data bus from D0 to D15 for each external space. When applying a high-level ("H") signal to the BYTE pin, the data bus accessing the external memory space 3 becomes an 8-bit data bus after reset. When applying a low-level ("L") signal to the BYTE pin, the data bus accessing the external memory space 3 becomes the 16-bit data bus.

When changing single-chip mode to memory expansion mode, the address bus is in an indeterminate state until the microcomputer accesses an external memory space.

7.2.2 Chip-Select Signal

Chip-select signal shares pins with A20 to A22 and $\overline{A23}$. The PM11 and PM10 bits in the PM1 register determine which \overline{CS} area is accessed and how many chip-select signals are output. A maximum of four chip-select signals can be output.

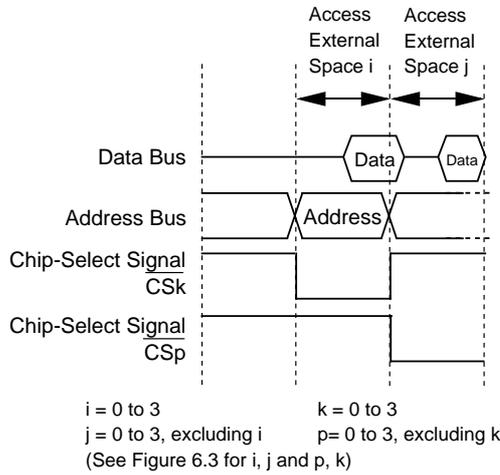

In microprocessor mode, no chip-select signal, aside from $\overline{A23}$ which can perform as a chip-select signal, is output after reset.

The chip-select signal becomes "L" while the microcomputer is accessing the external \overline{CS}_i area (i=0 to 3). It becomes "H" while the microcomputer is accessing other external memory space.

Figure 7.2 shows an example of the address bus and chip-select signal output.

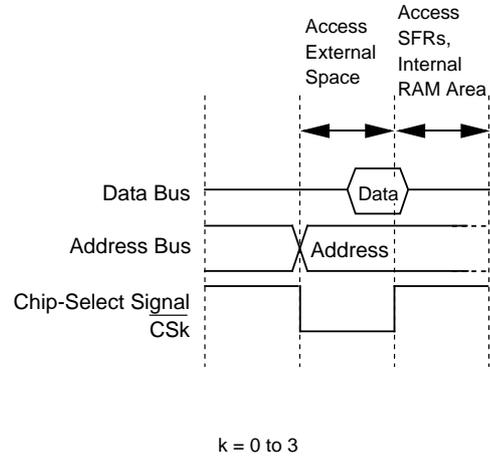

Example 1:

When the microcomputer accesses the external space *j* specified by another chip-select signal in the next cycle after having accessed the external space *i*, both address bus and chip-select signal change.

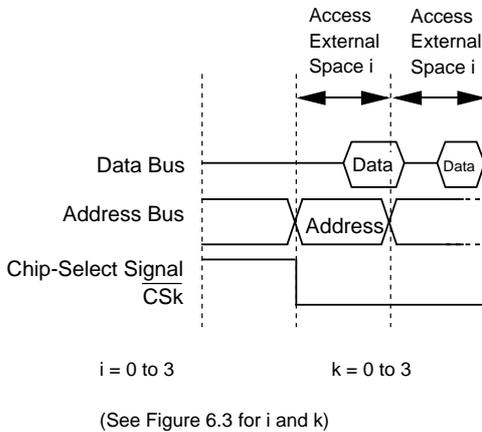

Example 2:

When the microcomputer accesses SFRs or the internal RAM area in the next cycle after having accessed an external space, the chip-select signal changes but the address bus does not.

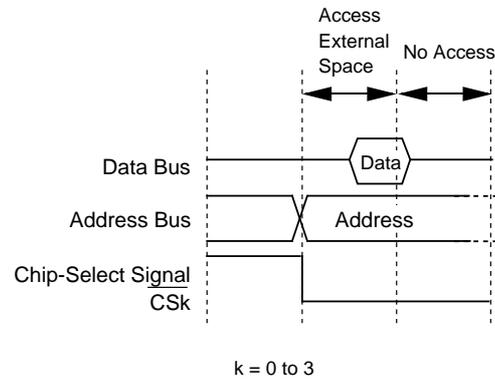

Example 3:

When the microcomputer accesses the space *i* specified by the same chip-select signal in the next cycle after having accessed the external space *i*, the address bus changes but the chip-select signal does not.

Example 4:

When the microcomputer does not access any space in the next cycle after having accessed an external space (no pre-fetch of an instruction is generated), neither address bus nor chip-select signal changes.

NOTE:

1. The above applies to the address bus and chip-select signal in two consecutive cycles. By combining these examples, a chip-select signal added by two or more cycles may be output.

Figure 7.2 Address Bus and Chip-Select Signal Outputs (Separate Bus)

7.2.3 Read and Write Signals

When using a 16-bit data bus, the PM02 bit in the PM0 register selects a combination of the " \overline{RD} , \overline{WR} and \overline{BHE} " signals or the " \overline{RD} , \overline{WRL} and \overline{WRH} " signals to determine the read or write signal. When the DS3 to DS0 bits in the DS register are set to "0" (8-bit data bus), set the PM02 bit to "0" ($\overline{RD}/\overline{WR}/\overline{BHE}$). When any of the DS3 to DS0 bits are set to "1" (16-bit data bus) to access an 8-bit space, the combination of " \overline{RD} , \overline{WR} and \overline{BHE} " is automatically selected regardless of the PM02 bit setting. Tables 7.3 and 7.4 list each signal operation.

The \overline{RD} , \overline{WR} and \overline{BHE} signals are combined for the read or write signal after reset.

When changing the combination of " \overline{RD} , \overline{WRL} and \overline{WRH} ", set the PM02 bit first to write data to an external memory.

Table 7.3 \overline{RD} , \overline{WRL} and \overline{WRH} Signals

Data Bus	\overline{RD}	\overline{WRL}	\overline{WRH}	Status of External Data Bus
16 Bits	L	H	H	Read data
	H	L	H	Write 1-byte data to even address
	H	H	L	Write 1-byte data to odd address
	H	L	L	Write data to both even and odd addresses
8 Bits	H	L ⁽¹⁾	Not used	Write 1-byte data
	L	H ⁽¹⁾	Not used	Read 1-byte data

NOTE:

1. The \overline{WR} signal is used instead of the \overline{WRL} signal.

Table 7.4 \overline{RD} , \overline{WR} and \overline{BHE} Signals

Data Bus	\overline{RD}	\overline{WR}	\overline{BHE}	A0	Status of External Data Bus
16 Bits	H	L	L	H	Write 1-byte data to odd address
	L	H	L	H	Read 1-byte data from odd address
	H	L	H	L	Write 1-byte data to even address
	L	H	H	L	Read 1-byte data from even address
	H	L	L	L	Write data to both even and odd addresses
	L	H	L	L	Read data from both even and odd addresses
8 Bits	H	L	Not used	H / L	Write 1-byte data
	L	H	Not used	H / L	Read 1-byte data

7.2.4 Bus Timing

Bus cycle for the internal memory is basically one BCLK cycle. When the PM12 bit in the PM1 register is set to "1" (wait state), the bus cycles are two BCLK cycles.

Bus cycles for SFRs are basically two BCLK cycles. When the PM13 bit in the PM1 register is set to "1" (2 wait states), the bus cycles are three BCLK cycles.

Basic bus cycle for an external space is 2ϕ ($1\phi+1\phi$) to read and to write. Bus cycle is selected by the EWCRi register (i=0 to 3) from 12 types of separate bus settings and 7 types of multiplexed bus settings. If the EWCRi04 to EWCRi00 bits are set to "000112" ($1\phi+3\phi$), bus cycles are four BCLK cycles.

Figure 7.3 shows the EWCRi register. Figures 7.4 to 7.8 show bus timing in an external space.

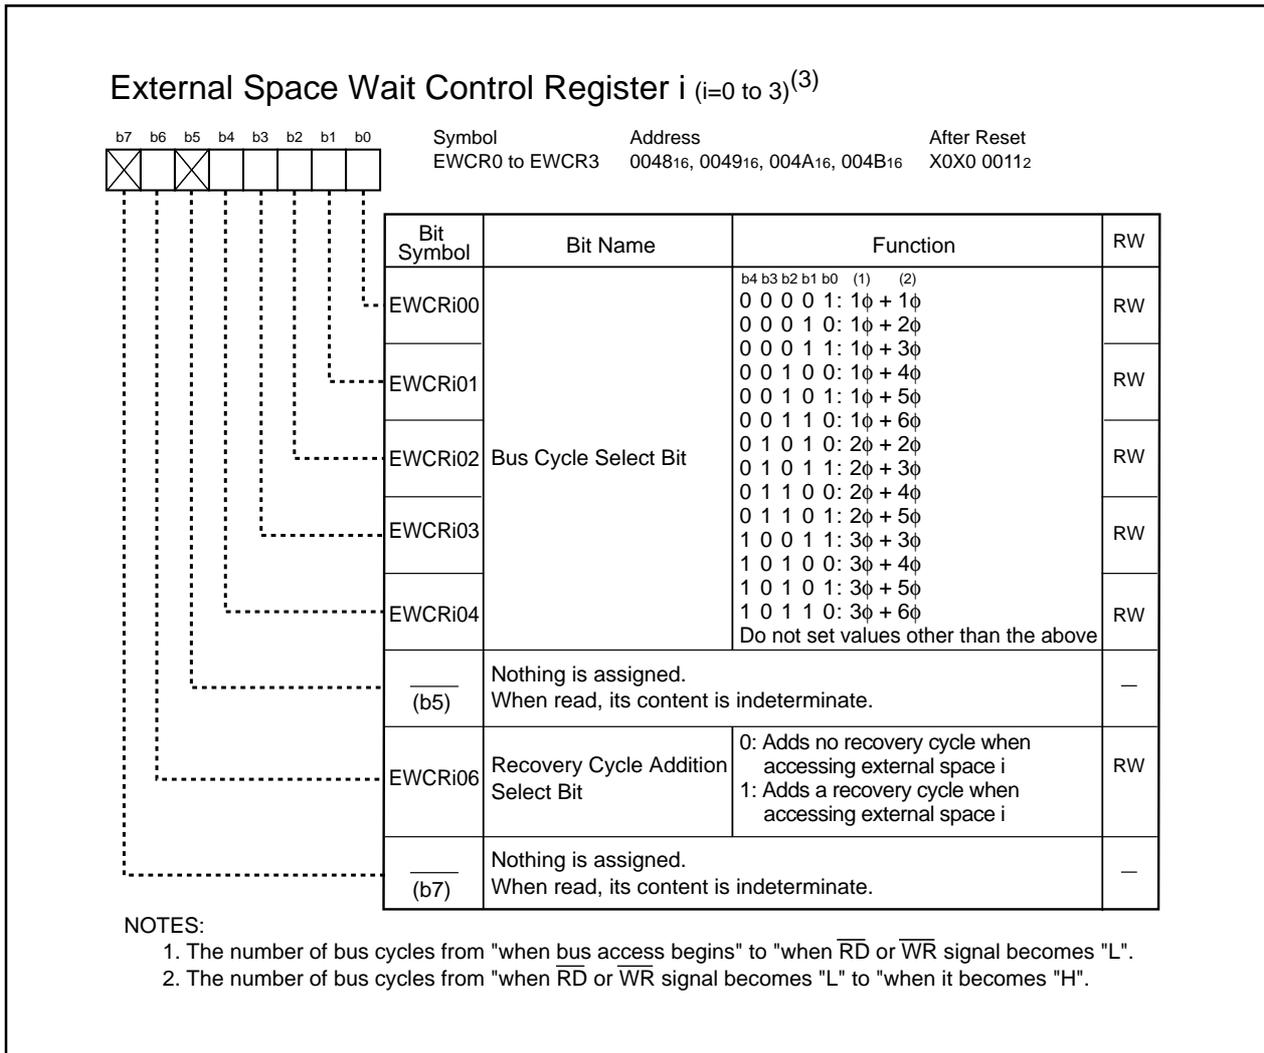

Figure 7.3 EWCR0 to EWCR3 Registers

Table 7.5 Software Wait State and Bus Cycle

Space	External Bus Status	PM1 Register		EWCRi Register (i=0 to 3)	Bus Cycles	
		PM13 Bit	PM12 Bit	EWCRi04 to EWCRi00 Bits		
SFRs	---	0	---	---	2 BCLK cycles	
		1			3 BCLK cycles	
Internal RAM	---	---	0	--	1 BCLK cycles	
			1		2 BCLK cycles	
External Memory	Separate Bus	---	---	000012	2 BCLK cycles	
				000102	3 BCLK cycles	
				000112	4 BCLK cycles	
				001002	5 BCLK cycles	
				001012	6 BCLK cycles	
				001102	7 BCLK cycles	
				010102	4 BCLK cycles	
				010112	5 BCLK cycles	
				011002	6 BCLK cycles	
				100112	6 BCLK cycles	
				101002	7 BCLK cycles	
				101102	9 BCLK cycles	
	Multiplexed Bus	---	---	---	010102	4 BCLK cycles
					010112	5 BCLK cycles
					011012	7 BCLK cycles
					100112	6 BCLK cycles
					101002	7 BCLK cycles
					101012	8 BCLK cycles
				101102	9 BCLK cycles	

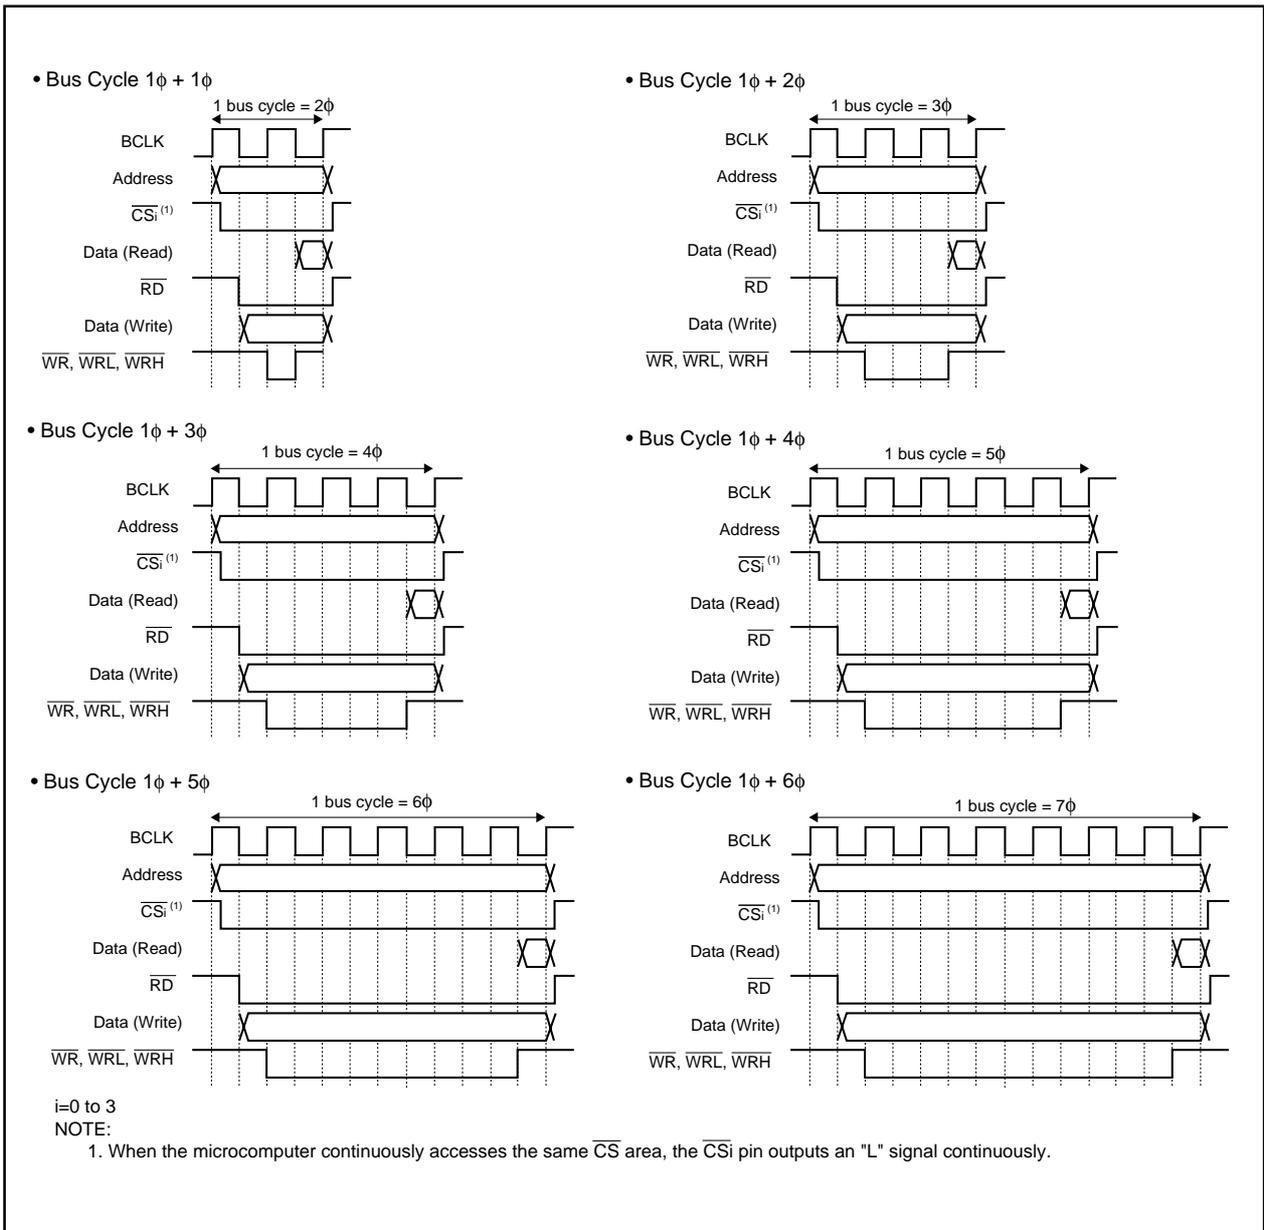

Figure 7.4 Bus Cycle with Separate Bus (1)

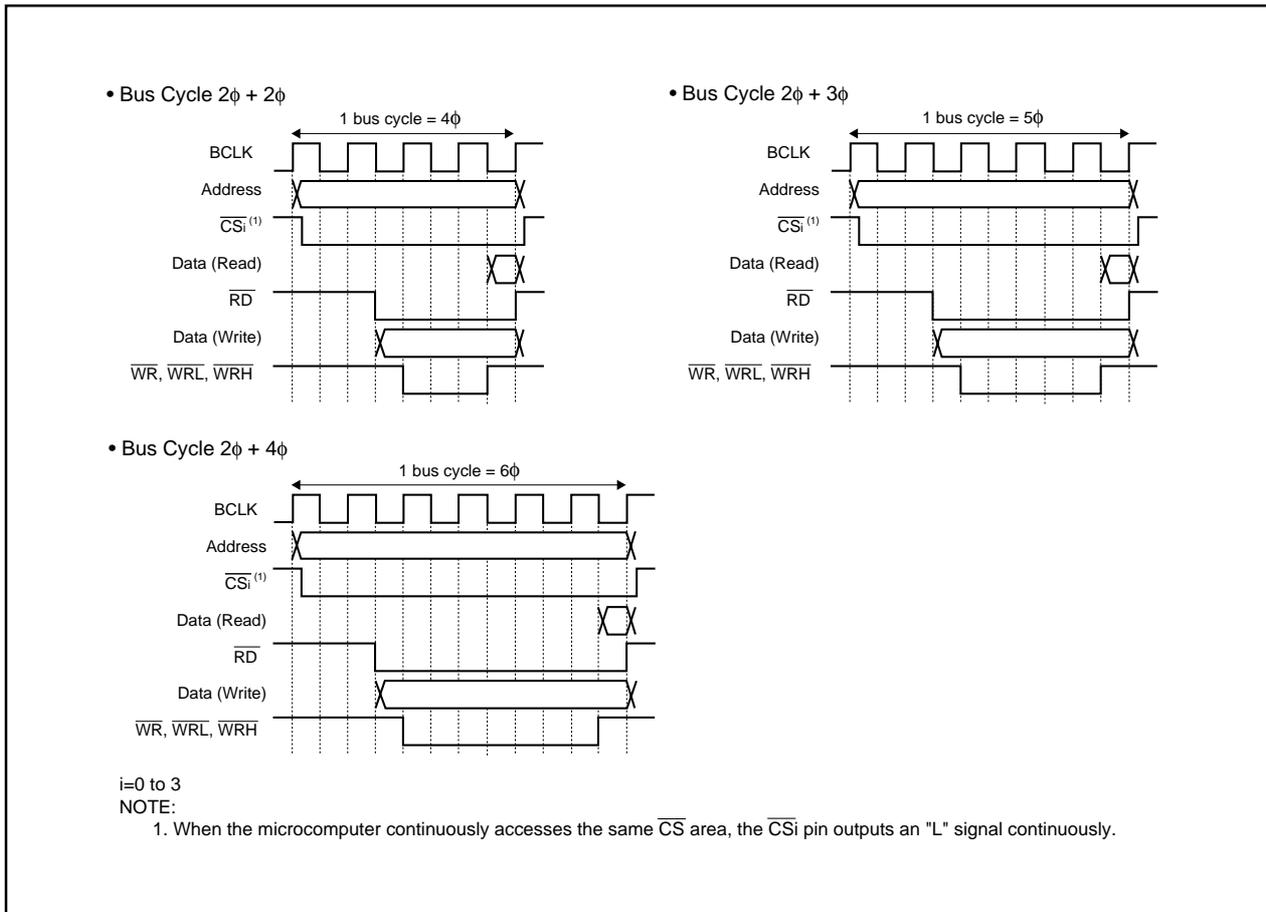

Figure 7.5 Bus Cycle with Separate Bus (2)

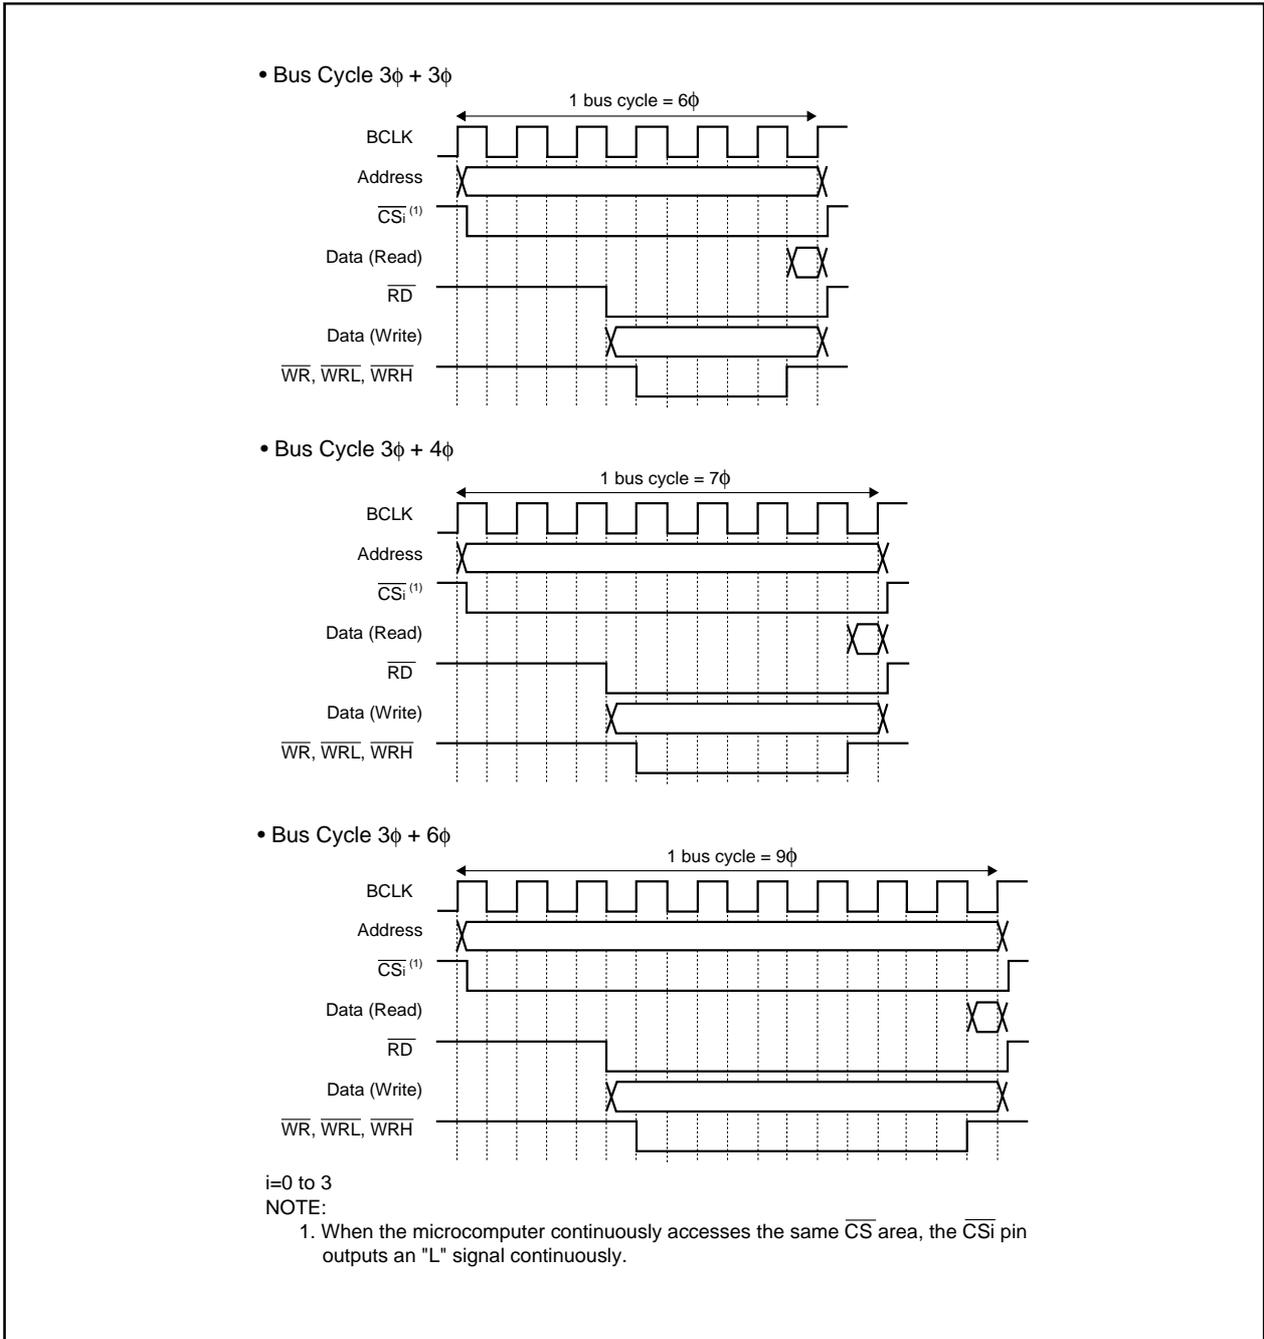

Figure 7.6 Bus Cycle with Separate Bus (3)

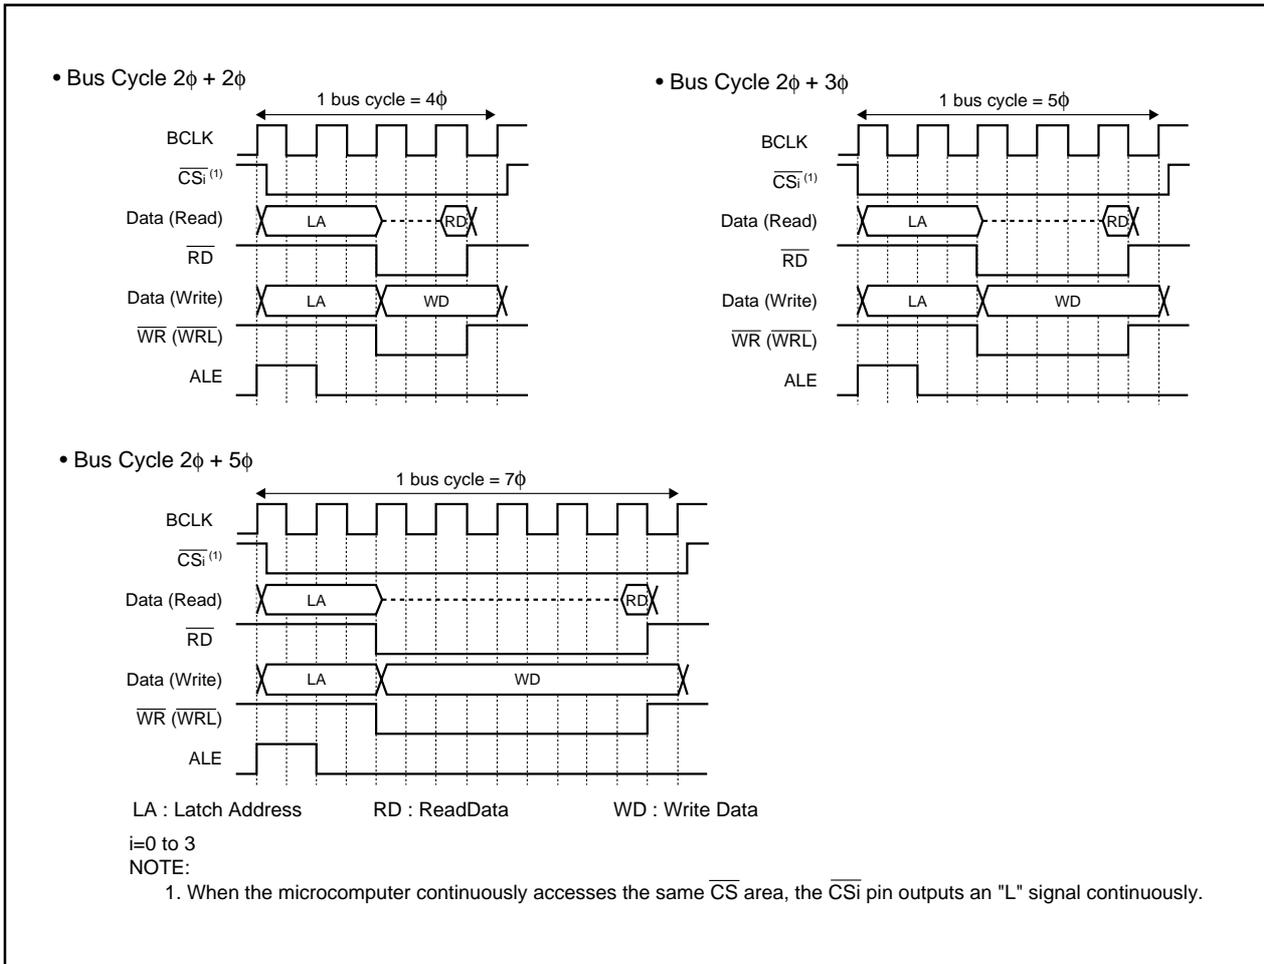

Figure 7.7 Bus Cycle with Multiplexed Bus (1)

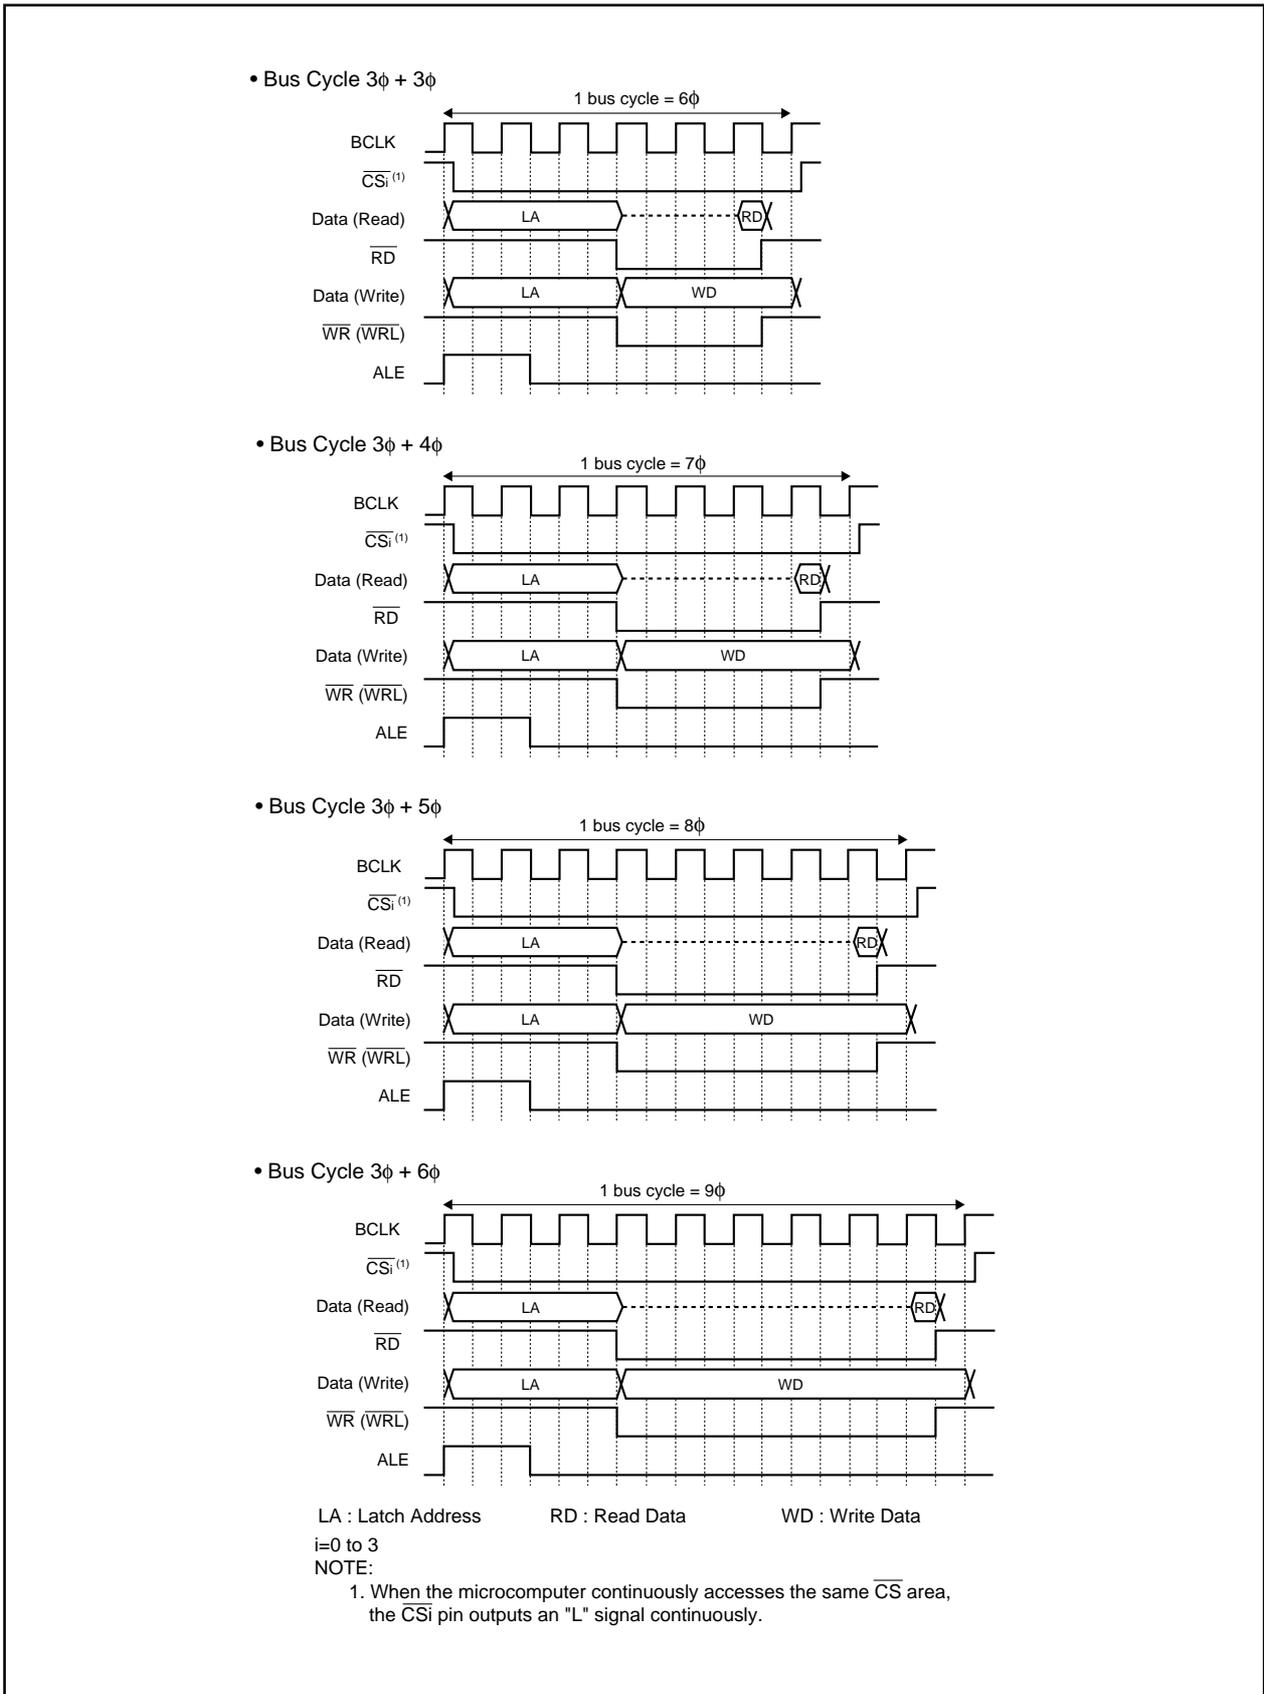

Figure 7.8 Bus Cycle with Multiplexed Bus (2)

7.2.4.1 Bus Cycle with Recovery Cycle Added

The EWCRi06 bit in the EWCRi register (i=0 to 3) determines whether the recovery cycle is added or not. In the recovery cycle, addresses and write data outputs are provided continuously (using the separate bus only). Devices, which take longer address hold time and data hold time to write data, are connectable.

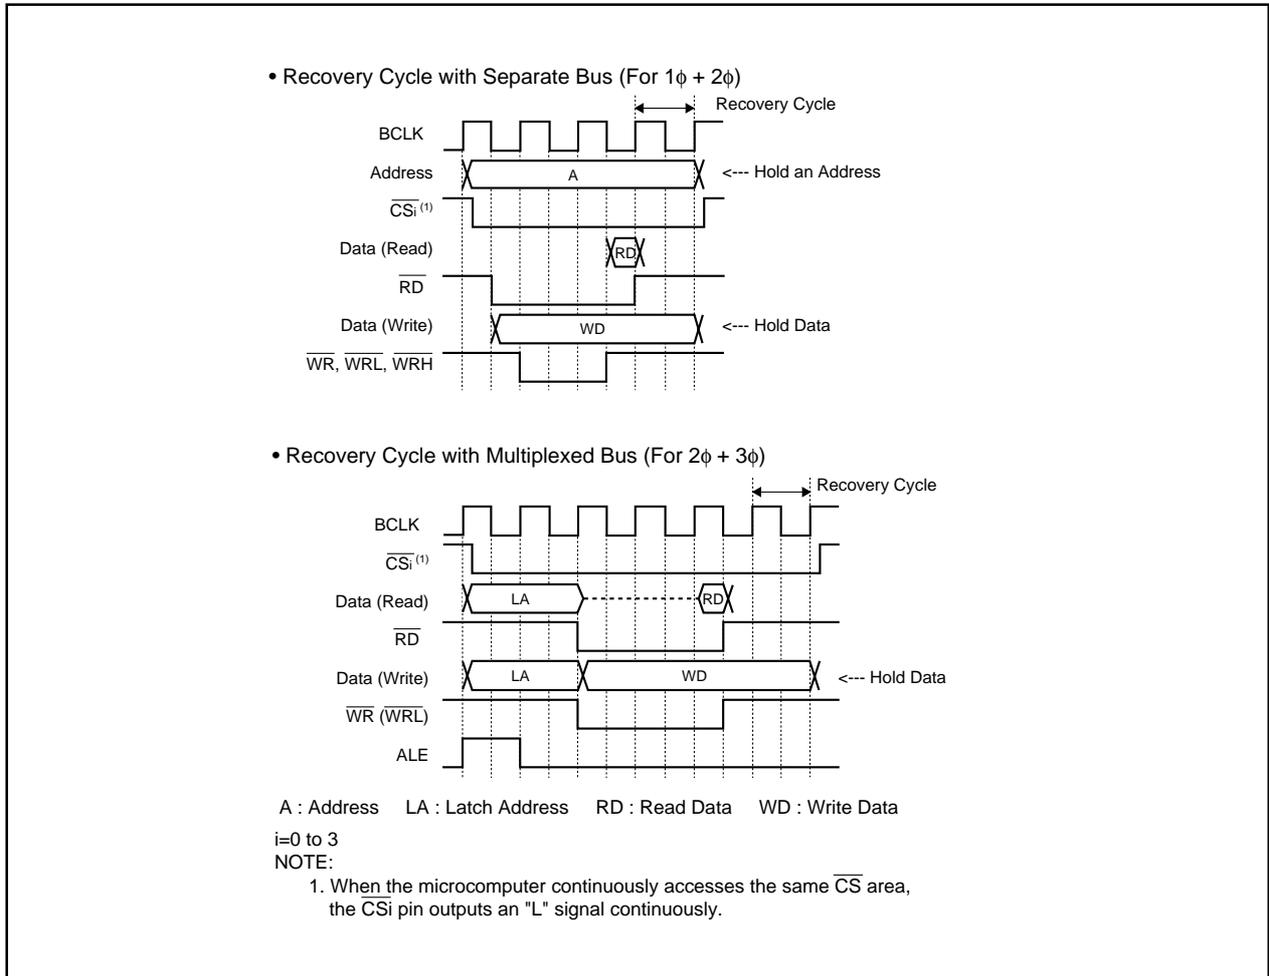

Figure 7.9 Recovery Cycle

7.2.5 ALE Signal

The ALE signal latches an address of the multiplexed bus. Latch an address on the falling edge of the ALE signal. The PM15 and PM14 bits in the PM1 register determine the output pin for the ALE signal. The ALE signal is output to internal space and external space.

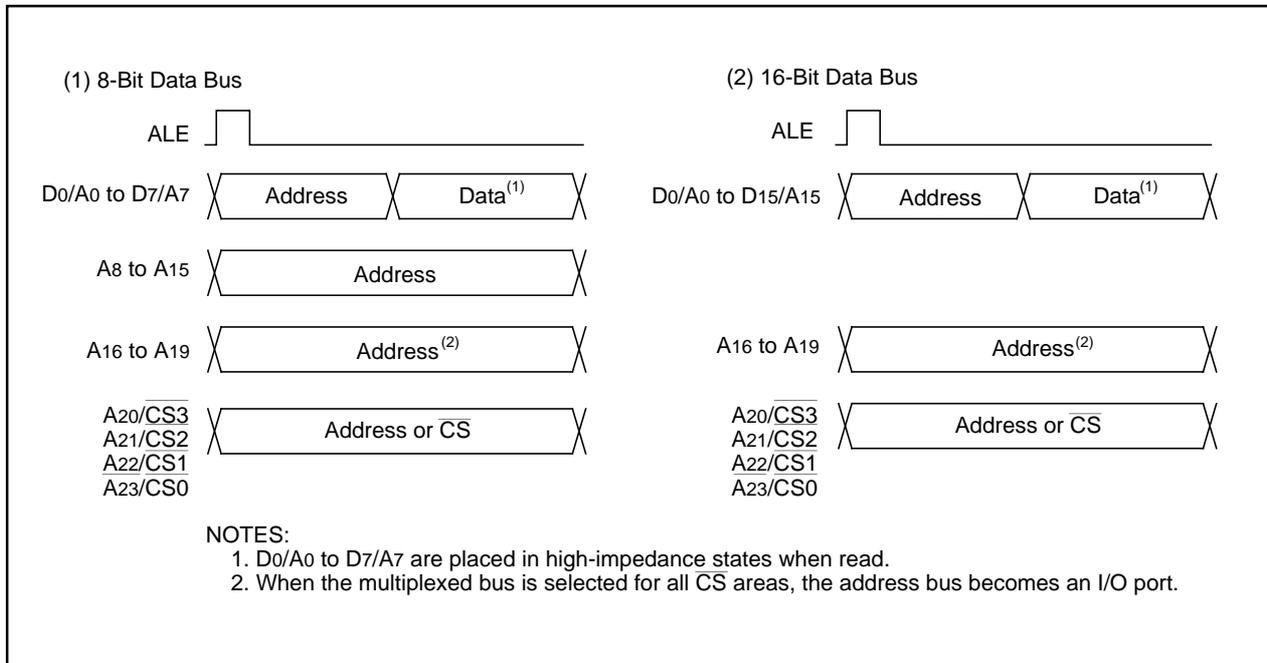

Figure 7.10 ALE Signal and Address/Data Bus

7.2.6 RDY Signal

The $\overline{\text{RDY}}$ signal facilitates access to external devices requiring longer access time. When a low-level ("L") signal is applied to the $\overline{\text{RDY}}$ pin on the falling edge of the last BCLK of the bus cycle, wait states are inserted into the bus cycle. When a high-level ("H") signal is applied to the $\overline{\text{RDY}}$ pin on the falling edge of BCLK, the bus cycle starts running again.

Table 7.6 lists microcomputer states when the $\overline{\text{RDY}}$ signal inserts wait states into the bus cycle. Figure 7.11 shows an example of the $\overline{\text{RD}}$ signal that is extended by the $\overline{\text{RDY}}$ signal.

Table 7.6 Microcomputer States in Wait State⁽¹⁾

Item	State
Oscillation	On
$\overline{\text{RD}}$ Signal, $\overline{\text{WR}}$ Signal, Address Bus, Data Bus, $\overline{\text{CS}}$, ALE Signal, $\overline{\text{HLDA}}$, Programmable I/O Ports	Maintains the same state as when $\overline{\text{RDY}}$ signal was received
Internal Peripheral Circuits	On

NOTE:

1. The $\overline{\text{RDY}}$ signal cannot be accepted immediately before software wait states are inserted.

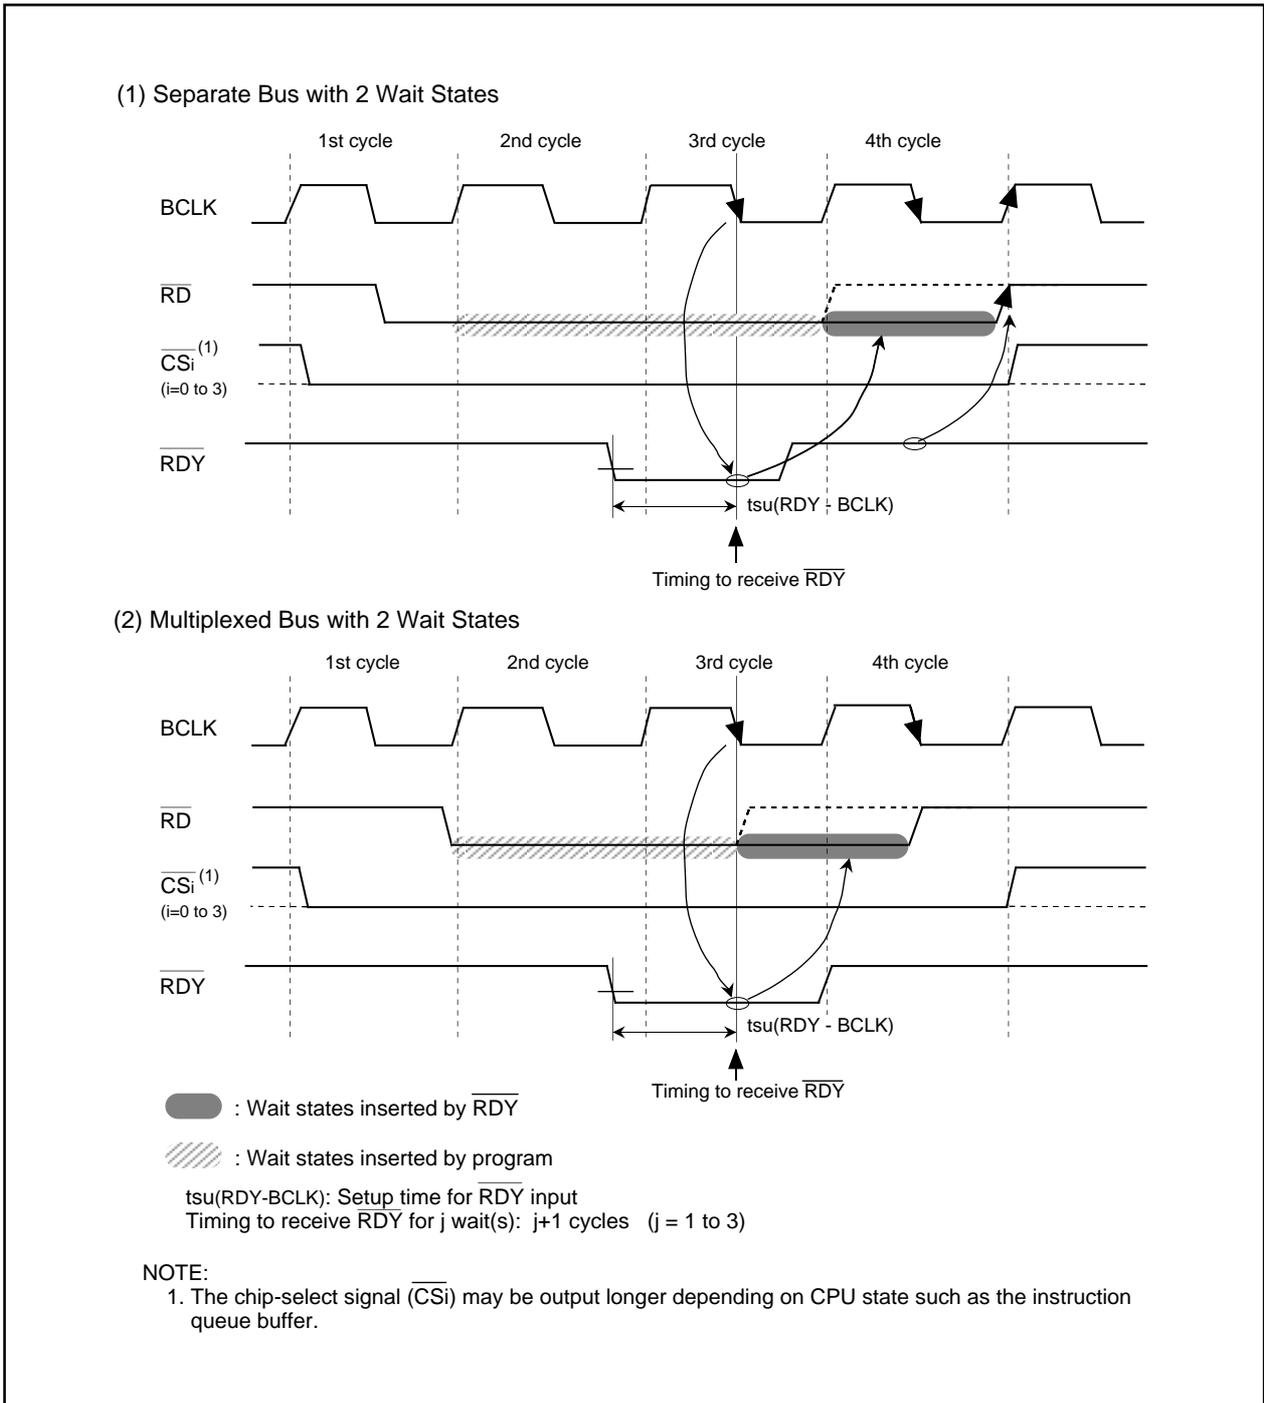

Figure 7.11 \overline{RD} Signal Output Extended by \overline{RDY} Signal

7.2.7 $\overline{\text{HOLD}}$ Signal

The $\overline{\text{HOLD}}$ signal transfers bus privileges from the CPU to external circuits. When a low-level ("L") signal is applied to the $\overline{\text{HOLD}}$ pin, the microcomputer enters a hold state after bus access is completed. While the $\overline{\text{HOLD}}$ pin is held "L", the microcomputer is in a hold state and the $\overline{\text{HLDA}}$ pin outputs an "L" signal.

Table 7.7 shows the microcomputer status in a hold state.

Bus is used in the following priority order: $\overline{\text{HOLD}}$, DMAC, CPU.

$\overline{\text{HOLD}} > \text{DMAC} > \text{CPU}$

Figure 7.12 Bus Priority Order

Table 7.7 Microcomputer Status in Hold State

Item	Status
Oscillation	On
$\overline{\text{RD}}$ Signal, $\overline{\text{WR}}$ Signal, Address Bus, Data Bus, CS, BHE	High-impedance
Programmable I/O Ports	Maintains the same state as when $\overline{\text{HOLD}}$ signal was received
$\overline{\text{HLDA}}$	Outputs "L"
Internal Peripheral Circuits	On (excluding the watchdog timer)
ALE Signal	Outputs "L"

7.2.8 External Bus Status when Accessing Internal Space

Table 7.8 shows external bus states when an internal space is accessed.

Table 7.8 External Bus States when Accessing Internal Space

Item	State when Accessing SFRs, Internal ROM, and Internal RAM	
Address Bus	Holds address of external space last accessed	
Data Bus	When Reading	High-impedance
	When Writing	High-impedance
$\overline{\text{RD}}$, $\overline{\text{WR}}$, $\overline{\text{WRL}}$, $\overline{\text{WRH}}$	Outputs "H"	
$\overline{\text{BHE}}$	Holds state of external space last accessed	
$\overline{\text{CS}}$	Outputs "H"	
ALE	Outputs ALE	

7.2.9 BCLK Output

The CPU clock operates the CPU. P53 outputs the CPU clock signal as BCLK when the PM07 bit in the PM0 register is set to "0" (BCLK) and the CM01 and CM00 bits in the CM0 register are set to "002" (I/O port P53).

No BCLK is output in single-chip mode. Refer to **8. Clock Generation Circuit** for details.

8. Clock Generation Circuit

8.1 Types of the Clock Generation Circuit

Four circuits are included to generate the system clock signal:

- Main clock oscillation circuit
- Sub clock oscillation circuit
- On-chip oscillator
- PLL frequency synthesizer

Table 8.1 lists specifications of the clock generation circuit. Figure 8.1 shows a block diagram of the clock generation circuit. Figures 8.2 to 8.8 show registers controlling the clock.

Table 8.1 Clock Generation Circuit Specifications

Item	Main Clock Oscillation Circuit	Sub Clock Oscillation Circuit	On-chip Oscillator	PLL Frequency Synthesizer
Use	CPU clock source, Peripheral function clock source	CPU clock source, Timer A and B clock source	CPU clock source, Peripheral function clock source	CPU clock source, Peripheral function clock source
Clock Frequency	Up to 32 MHz	32.768 kHz	Approx. 1 MHz	Up to 32 MHz (See Table 8.3)
Connectable Oscillator or Additional Circuit	Ceramic resonator Crystal oscillator	Crystal oscillator	---	---
Pins for Oscillator or for Additional Circuit	XIN, XOUT	XCIN, XCOU	---	---
Oscillation Stop / Restart Function	Available	Available	Available	Available
Oscillator State after Reset	Oscillating	Stopped	Stopped	Stopped
Other	Externally generated clock can be applied.	Externally generated clock can be applied.	When the main clock stops oscillating, the on-chip oscillator starts oscillating automatically and becomes clock source for the CPU and peripheral function.	---

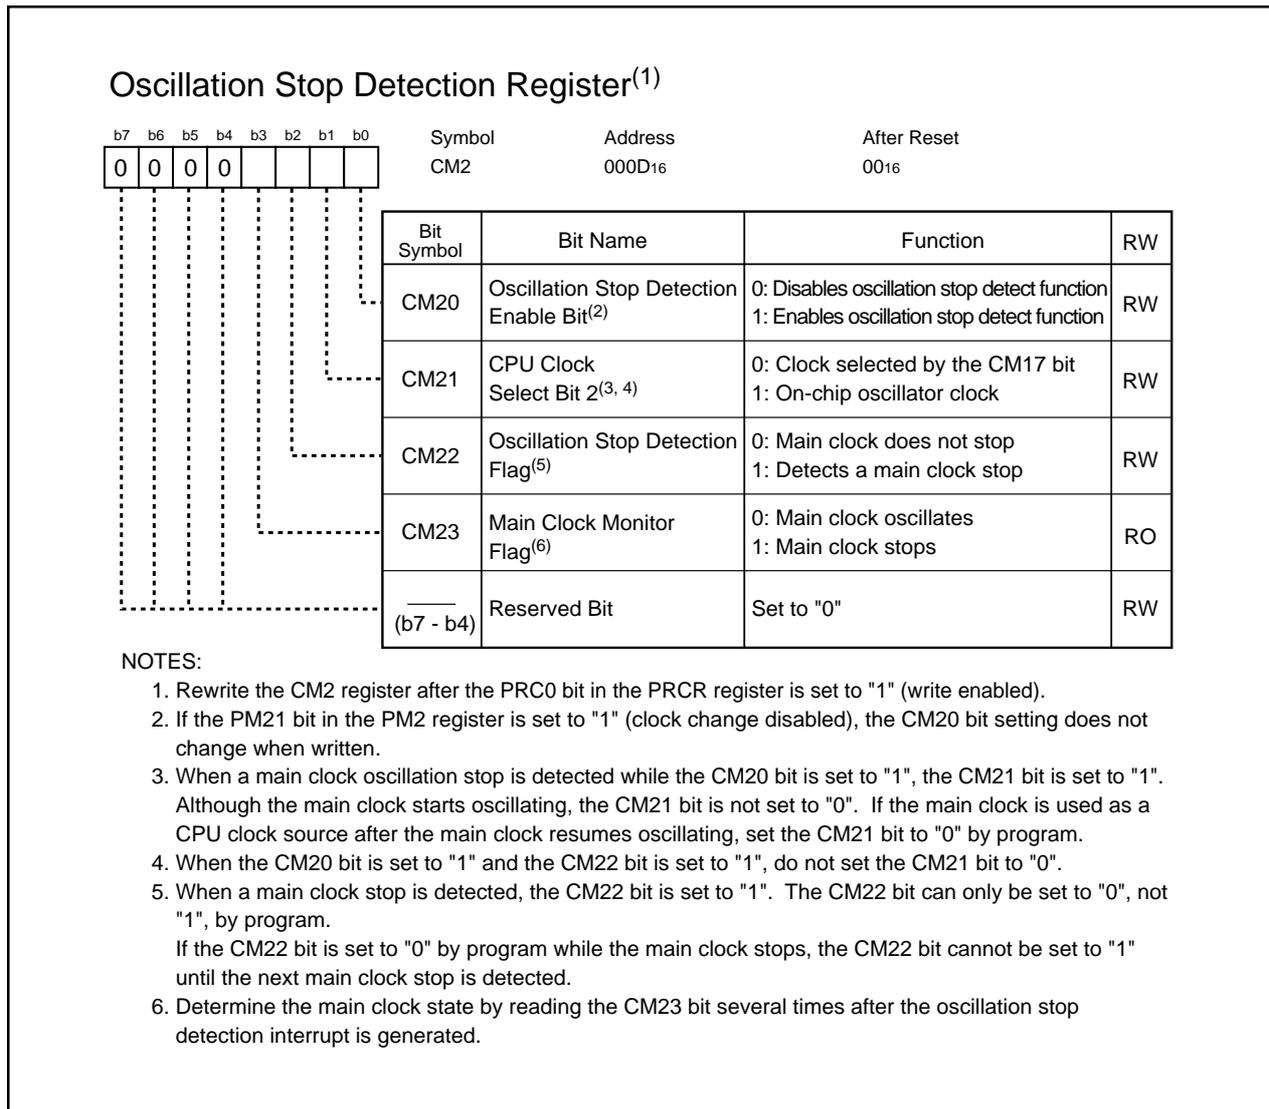

Figure 8.5 CM2 Register

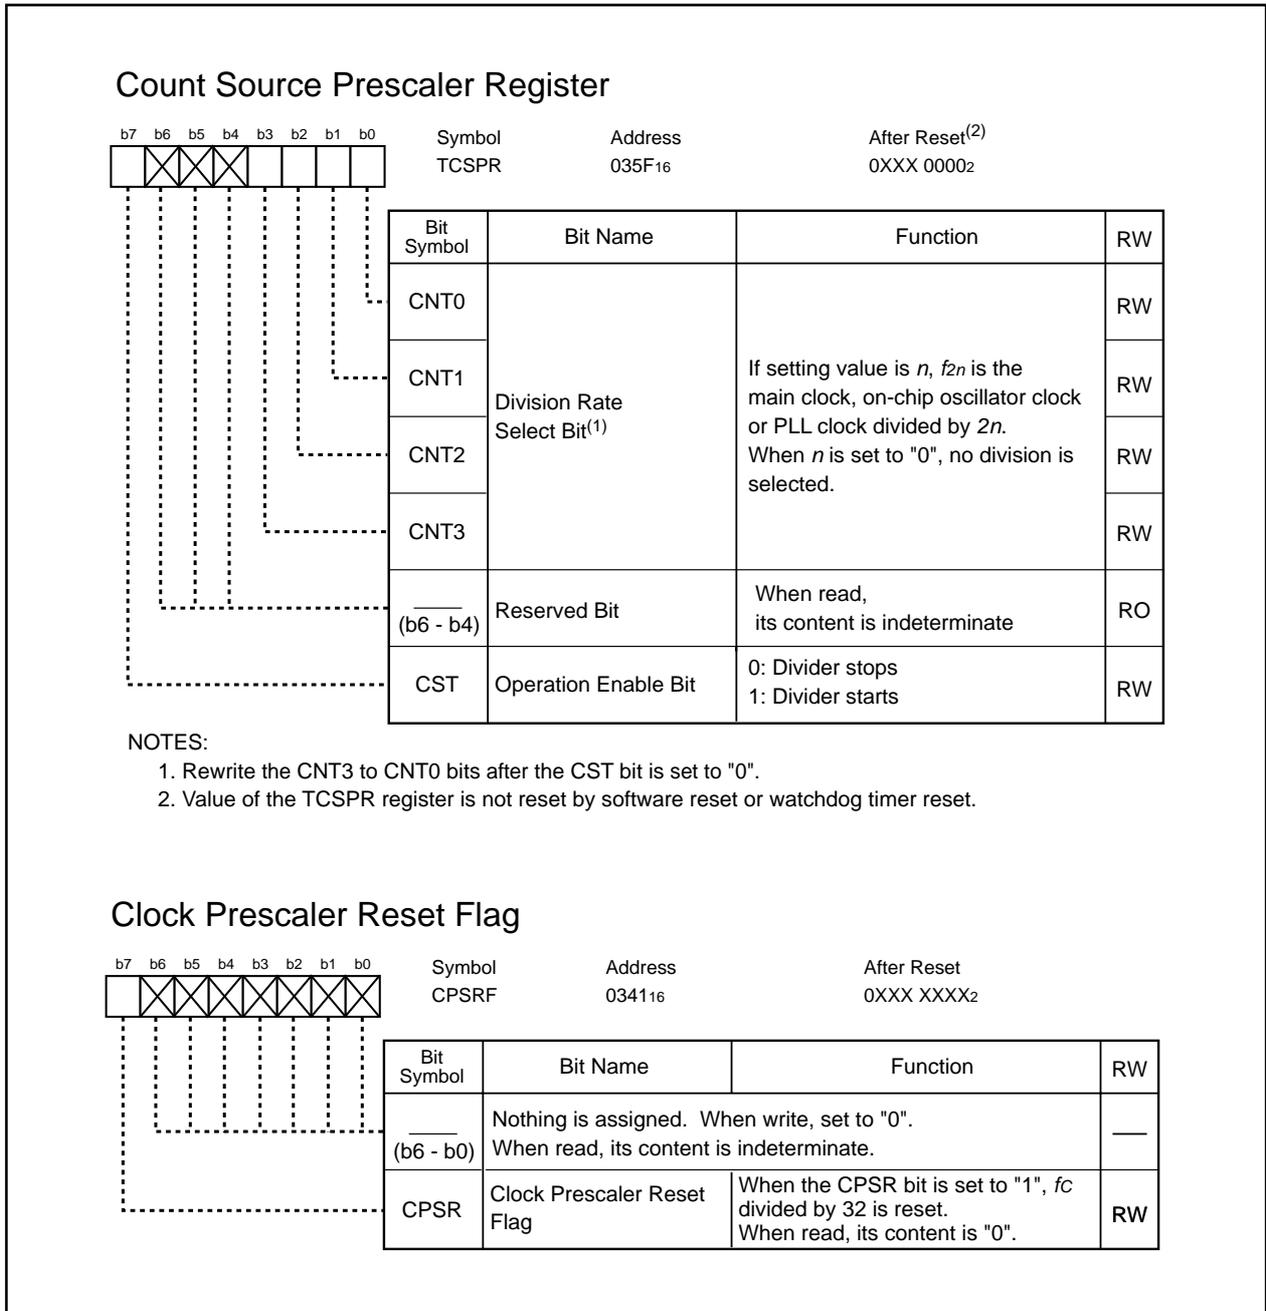

Figure 8.6 TCSR and CPSRF Registers

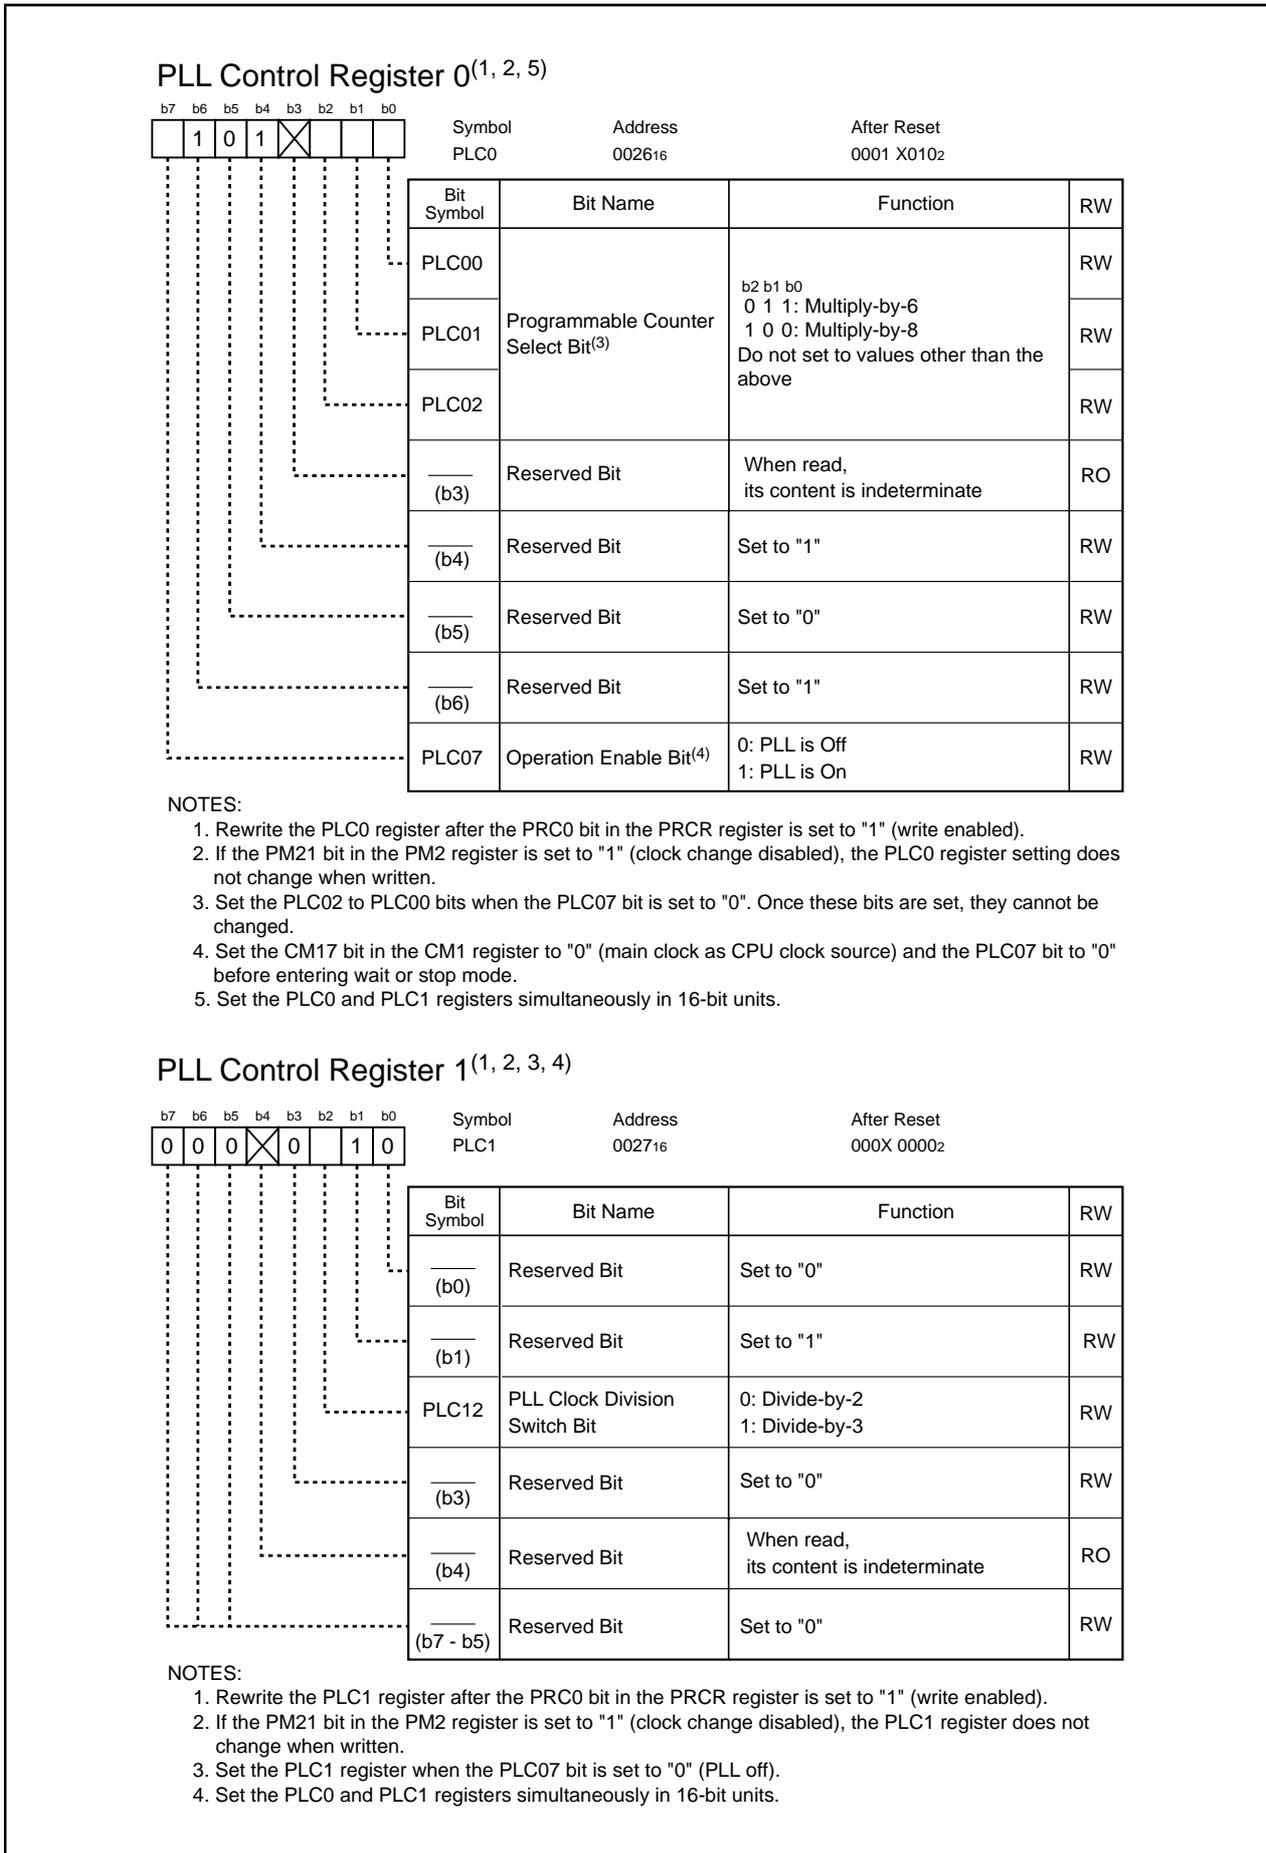

Figure 8.7 PLC0 and PLC1 Registers

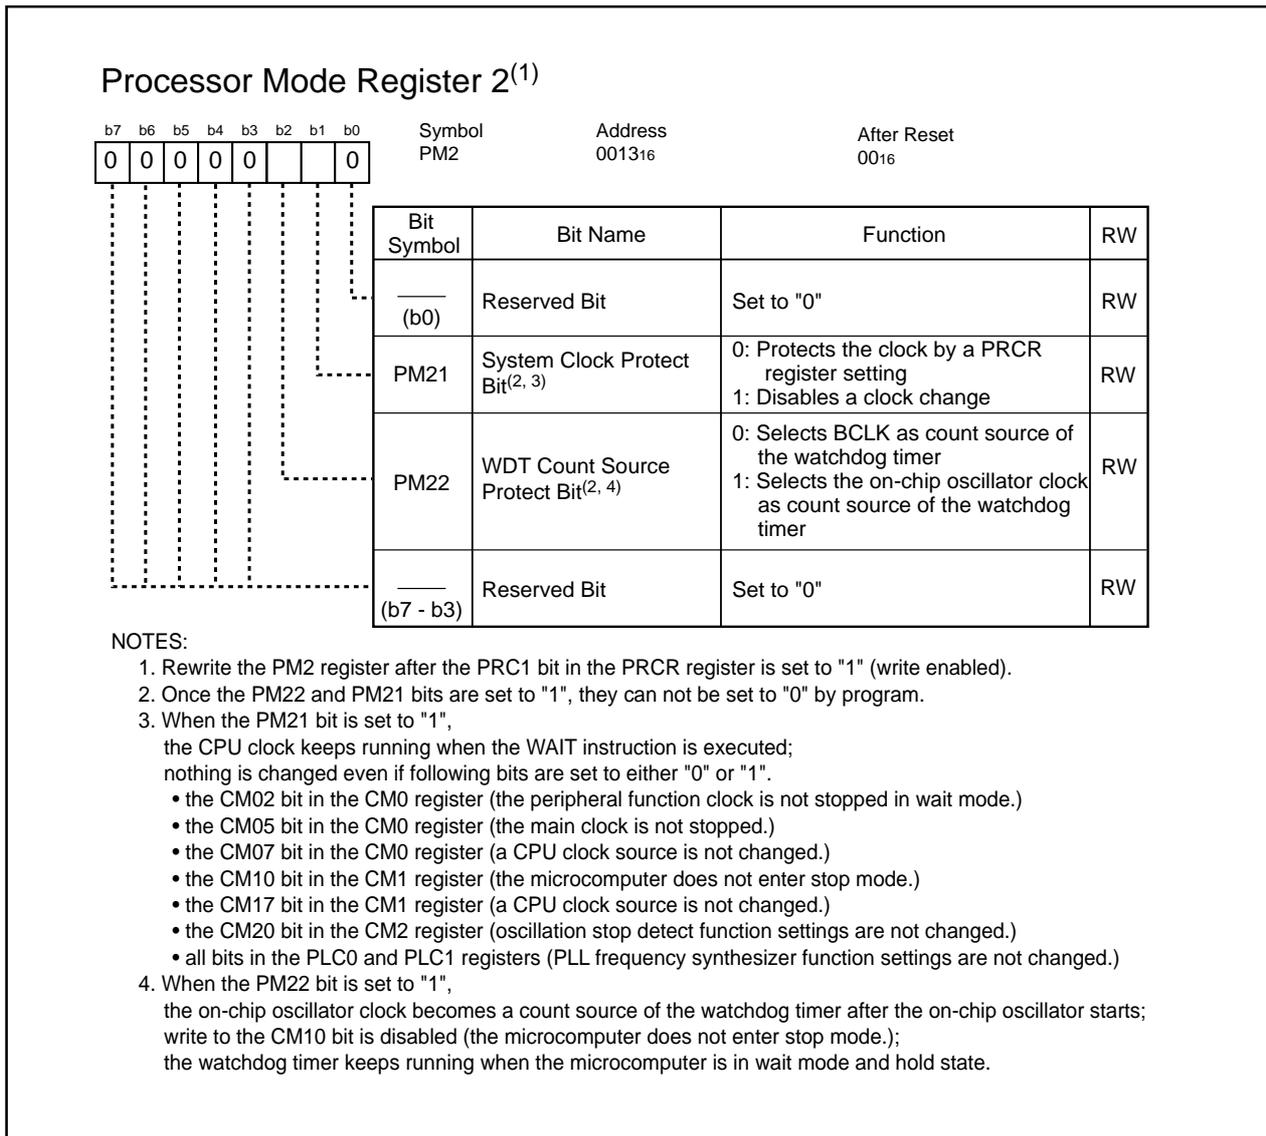

Figure 8.8 PM2 Register

8.1.1 Main Clock

Main clock oscillation circuit generates the main clock. The main clock becomes clock source of the CPU clock and peripheral function clock.

The main clock oscillation circuit is configured by connecting an oscillator or resonator between the XIN and XOUT pins. The circuit has a built-in feedback resistor. The feedback resistor is separated from the oscillation circuit in stop mode to reduce power consumption. An external clock can be applied to the XIN pin in the main clock oscillation circuit. Figure 8.9 shows an example of a main clock circuit connection. Circuit constants vary depending on each oscillator. Use the circuit constant recommended by each oscillator manufacturer.

The main clock divided-by-eight becomes a CPU clock source after reset.

To reduce power consumption, set the CM05 bit in the CM0 register to "1" (main clock stopped) after switching the CPU clock source to the sub clock or on-chip oscillator clock. In this case, the clock applied to XOUT becomes high ("H"). XIN is pulled up by XOUT via the feedback resistor which remains on. When an external clock is applied to the XIN pin, do not set the CM05 bit to "1".

All clocks, including the main clock, stop in stop mode. Refer to **8.5 Power Consumption Control** for details.

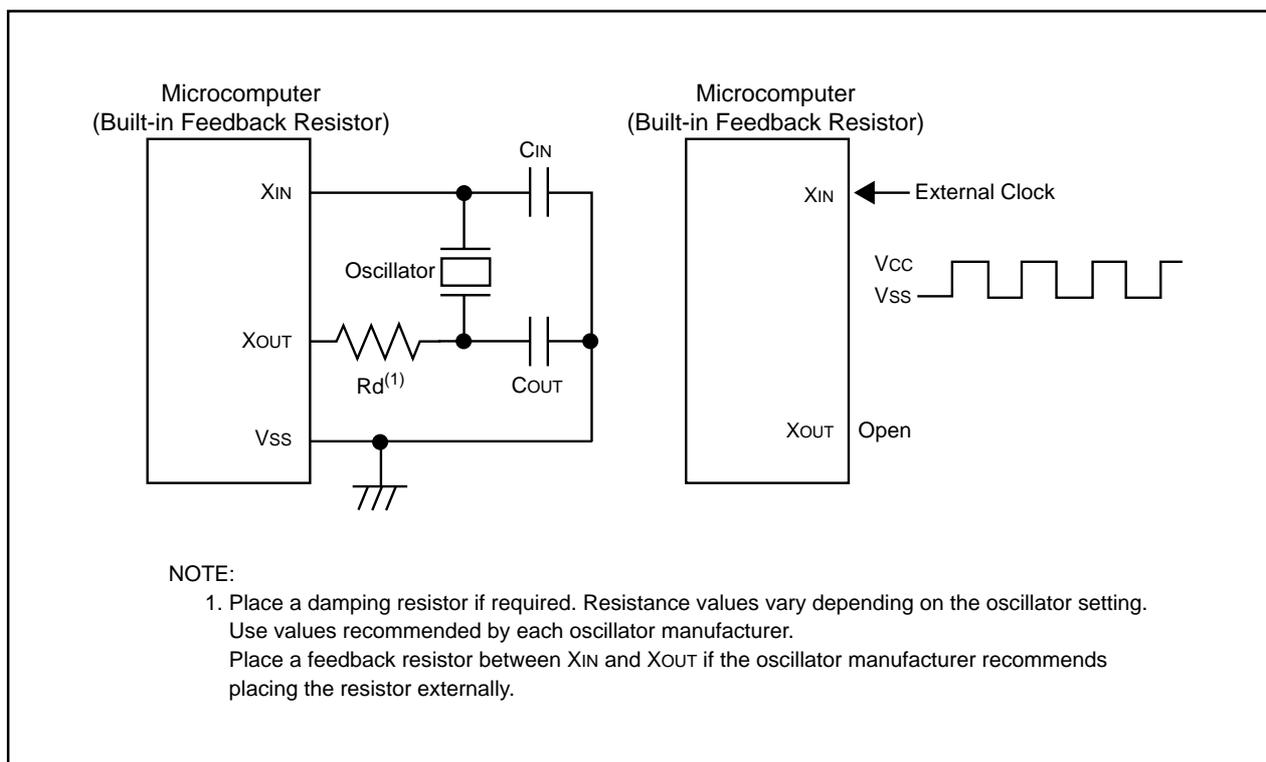

Figure 8.9 Main Clock Circuit Connection

8.1.2 Sub Clock

Sub clock oscillation circuit generates the sub clock. The sub clock becomes clock source of the CPU clock and for the timers A and B. The same frequency, f_c , as the sub clock can be output from the CLKOUT pin.

The sub clock oscillation circuit is configured by connecting a crystal oscillator between the XCIN and XCOUT pins. The circuit has a built-in feedback resistor. The feedback resistor is separated from the oscillation circuit in stop mode to reduce power consumption. An external clock can be applied to the XCIN pin. Figure 8.10 shows an example of a sub clock circuit connection. Circuit constants vary depending on each oscillator. Use the circuit constant recommended by each oscillator manufacturer.

The sub clock stops after reset. The feedback resistor is separated from the oscillation circuit. When the PD8_6 and PD8_7 bits in the PD8 register are set to "0" (input mode) and the PU25 bit in the PUR2 register is set to "0" (no pull-up), set the CM04 bit in the CM0 register to "1" (XCIN-XCOUT oscillation function). The sub clock oscillation circuit starts oscillating. To apply an external clock to the XCIN pin, set the CM04 bit to "1" when the PD8_7 bit is set to "0" and the PU25 bit to "0". The clock applied to the XCIN pin becomes a clock source of the sub clock.

When the CM07 bit in the CM0 register is set to "1" (sub clock) after the sub clock oscillation has stabilized, the sub clock becomes a CPU clock source.

All clocks, including the sub clock, stop in stop mode. Refer to **8.5 Power Consumption Control** for details.

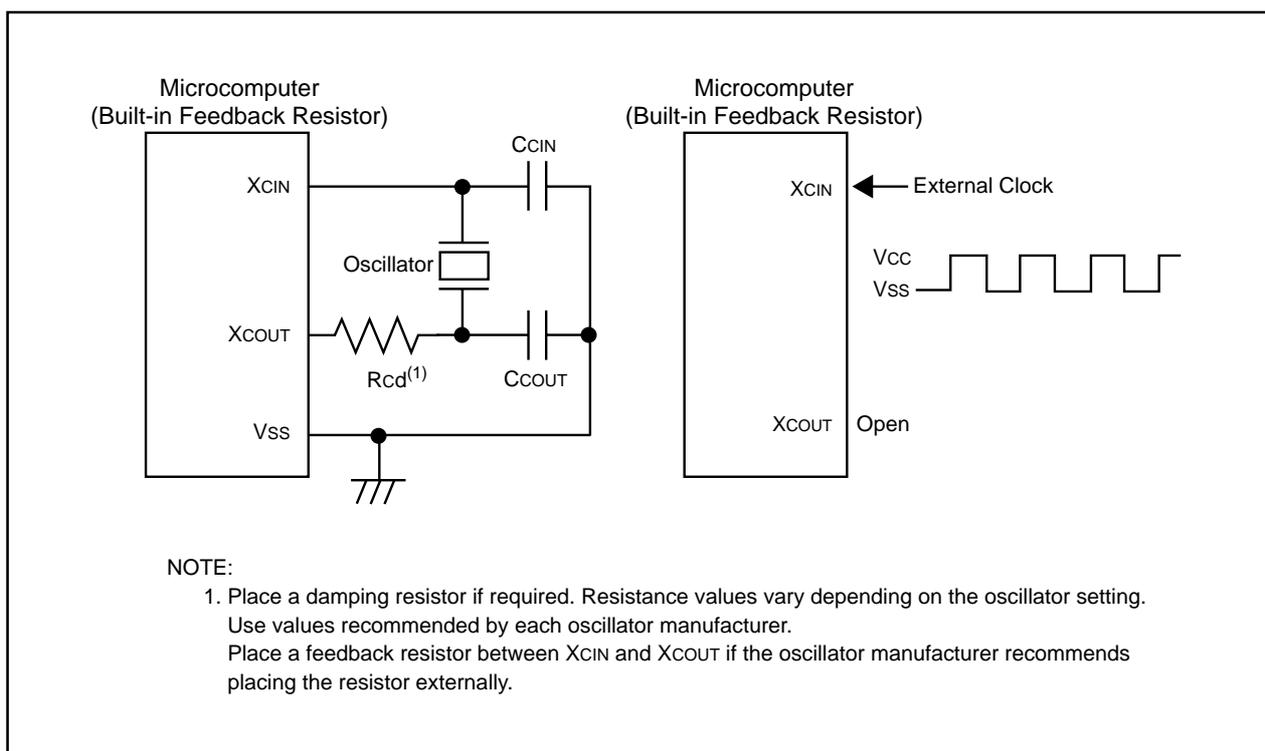

Figure 8.10 Sub Clock Circuit Connection

8.1.3 On-Chip Oscillator Clock

On-chip oscillator generates the on-chip oscillator clock. The 1-MHz on-chip oscillator clock becomes a clock source of the CPU clock and peripheral function clock.

The on-chip oscillator clock stops after reset. When the CM21 bit in the CM2 register is set to "1" (on-chip oscillator clock), the on-chip oscillator starts oscillating. Instead of the main clock, the on-chip oscillator clock becomes clock source of the CPU clock and peripheral function clock.

Table 8.2 shows bit settings for on-chip oscillator start condition.

Table 8.2 Bit Settings for On-Chip Oscillator Start Condition

CM2 Register	PM2 Register	Used as
CM21 Bit	PM22 Bit	
1	0	CPU clock source or peripheral function clock source
0	1	Watchdog timer operating clock source (The clock keeps running when entering stop mode.)

8.1.3.1 Oscillation Stop Detect Function

When the main clock is terminated by external source, the on-chip oscillator automatically starts oscillating to generate another clock.

When the CM 20 bit in the CM2 register is set to "1" (oscillation stop detect function enabled), an oscillation stop detection interrupt request is generated as soon as the main clock stops. Simultaneously, the on-chip oscillator starts oscillating. Instead of the main clock, the on-chip oscillator clock becomes clock source for the CPU clock and peripheral function clock. Associated bits are set as follows:

- The CM21 bit is set to "1" (on-chip oscillator clock becomes a clock source of the CPU clock.)
- The CM22 bit is set to "1" (main clock stop is detected.)
- The CM23 bit is set to "1" (main clock stops.) (See **Figure 8.14**)

8.1.3.2 How to Use Oscillation Stop Detect Function

- The oscillation stop detection interrupt shares vectors with the watchdog timer interrupt and the low voltage detection interrupt. When these interrupts are used simultaneously, read the CM22 bit with an interrupt routine to determine if an oscillation stop detection interrupt request has been generated.
- When the main clock resumes running after an oscillation stop is detected, set the main clock as clock source of the CPU clock and peripheral function clock. Figure 8.11 shows the procedure to switch the on-chip oscillator clock to the main clock.
- In low-speed mode, when the main clock is stopped by setting the CM20 bit to "1", the oscillation stop detection interrupt request is generated. Simultaneously, the on-chip oscillator starts oscillating. The sub clock remains the CPU clock source. The on-chip oscillator clock becomes a clock source for the peripheral function clock.
- When the peripheral function clock stops running, the oscillation stop detect function is also disabled. To enter wait mode while the oscillation stop detect function is in use, set the CM02 bit in the CM0 register to "0" (peripheral clock does not stop in wait mode).
- The oscillation stop detect function is provided to handle main clock stop caused by external source. Set the CM20 bit to "0" (oscillation stop detect function disabled) when the main clock is terminated by program, i.e., entering stop mode or setting the CM05 bit to "1" (main clock oscillation stop).
- When the main clock frequency is 2 MHz or less, the oscillation stop detect function is not available. Set the CM20 bit to "0".

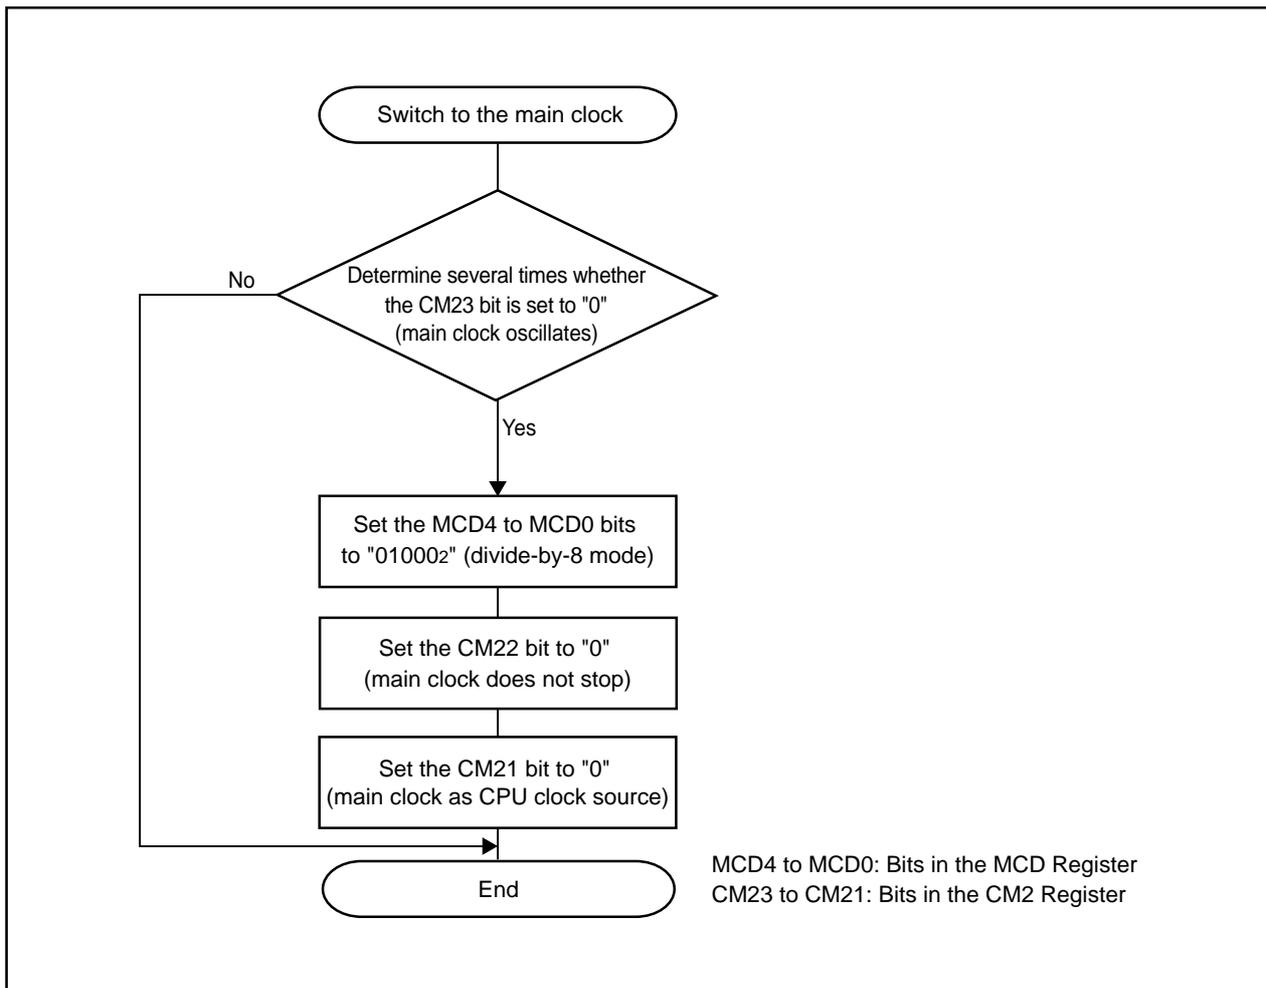

Figure 8.11 Switching Procedure from On-chip Oscillator Clock to Main Clock

8.1.4 PLL Clock

The PLL frequency synthesizer generates the PLL clock based on the main clock. The PLL clock can be used as clock source for the CPU clock and peripheral function clock.

The PLL frequency synthesizer stops after reset. When the PLC07 bit is set to "1" (PLL on), the PLL frequency synthesizer starts operating. Wait $t_{su(PLL)}$ ms for the PLL clock to stabilize.

The PLL clock can either be the clock output from the voltage controlled oscillator (VCO) divided-by-2 or divided-by-3. When the PLL clock is used as a clock source for the CPU clock or peripheral function clock, set each bit as is shown in Table 8.3. Figure 8.12 shows the procedure to use the PLL clock as the CPU clock source.

To enter wait or stop mode, set the CM17 bit to "0" (main clock as CPU clock source), set the PLC07 bit in the PLC0 register to "0" (PLL off) and then enter wait or stop mode.

Table 8.3 Bit Settings to Use PLL Clock as CPU Clock Source

f(X _{IN})	PLC0 Register			PLC1 Register	PLL Clock
	PLC02 Bit	PLC01 Bit	PLC00 Bit	PLC12 Bit	
10 MHz	0	1	1	0	30 MHz
				1	20 MHz
8 MHz	1	0	0	0	32 MHz
				1	21.3 MHz

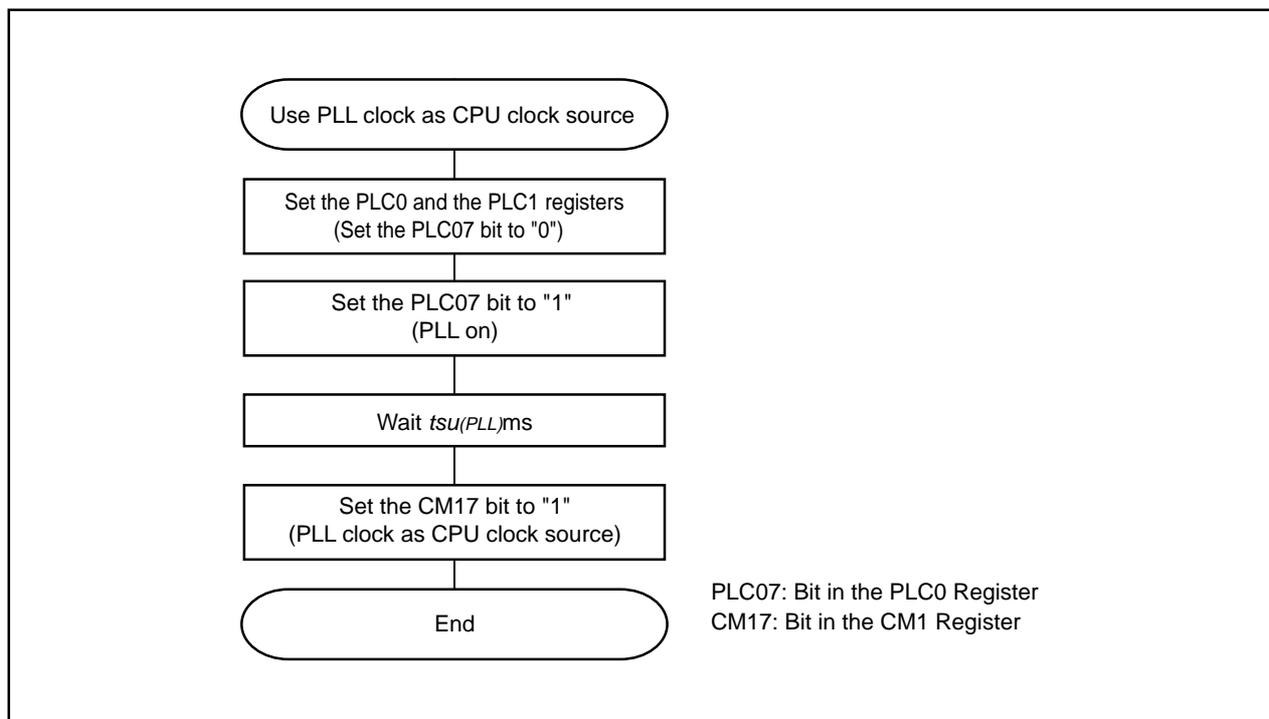

Figure 8.12 Procedure to Use PLL Clock as CPU Clock Source

8.2 CPU Clock and BCLK

The CPU operating clock is referred to as the CPU clock. The CPU clock is also a count source for the watchdog timer. After reset, the CPU clock is the main clock divided-by-8. In memory expansion or micro-processor mode, the clock having the same frequency as the CPU clock can be output from the BCLK pin as BCLK. Refer to **8.4 Clock Output Function** for details.

The main clock, sub clock, on-chip oscillator clock or PLL clock can be selected as a clock source for the CPU clock. Table 8.4 shows CPU clock source and bit settings.

When the main clock, on-chip oscillator clock or PLL clock is selected as a clock source of the CPU clock, the selected clock divided-by-1 (no division), -2, -3, -4, -6, -8, -10, -12, -14 or -16 becomes the CPU clock. The MCD4 to MCD0 bits in the MCD register select the clock division.

When the microcomputer enters stop mode or low-power consumption mode (except when the on-chip oscillator clock is the CPU clock), the MCD4 to MCD0 bits are set to "010002" (divide-by-8 mode). Therefore, when the main clock starts running, the CPU clock enters medium-speed mode (divide-by-8).

Table 8.4 CPU Clock Source and Bit Settings

CPU Clock Source	CM0 Register	CM1 Register	CM2 Register
	CM07 Bit	CM17 Bit	CM21 Bit
Main Clock	0	0	0
Sub Clock	1	0	0
On-Chip Oscillator Clock	0	0	1
PLL Clock	0	1	0

8.3 Peripheral Function Clock

The peripheral function clock becomes an operating clock or count source for peripheral functions excluding the watchdog timer.

8.3.1 f₁, f₈, f₃₂ and f_{2n}

f₁, f₈ and f₃₂ are the peripheral function clock, selected by the CM21 bit, divided-by-1, -8, or -32. The PM27 and PM26 bits in the PM2 register selects a f_{2n} count source from the peripheral clock, X_{IN} clock, and the on-chip oscillator clock. The CNT3 to CNT0 bits in the TCSPR register selects a f_{2n} division. (n=0 to 15. No division when n=0.)

f₁, f₈, f₃₂ and f_{2n} stop when the CM02 bit in the CM0 register to "1" (peripheral function stops in wait mode) to enter wait mode or when in low-power consumption mode.

f₁, f₈ and f_{2n} are used as an operating clock of the serial I/O and count source of the timers A and B. f₁ is also used as an operating clock for the intelligent I/O.

The CLKOUT pin outputs f₈ and f₃₂. Refer to **8.4 Clock Output Function** for details.

8.3.2 f_{AD}

f_{AD} is an operating clock for the A/D converter and has the same frequency as either the main clock⁽¹⁾ or the on-chip oscillator clock. The CM21 bit determines which clock is selected.

If the CM02 bit is set to "1" (peripheral function stop in wait mode) to enter wait mode, f_{AD} stops. f_{AD} also stops in low-power consumption mode.

NOTE:

1. The PLL clock, instead of the main clock, when the CM17 bit is set to "1" (PLL clock).

8.3.3 fc32

fc32 is the sub clock divided by 32. fc32 is used as a count source for the timers A and B. fc32 is available when the sub clock is running.

8.4 Clock Output Function

The CLKOUT pin outputs fc, f8 or f32.

In memory expansion mode or microprocessor mode, a clock having the same frequency as the CPU clock can be output from the BCLK pin as BCLK.

Table 8.5 lists CLKOUT pin function in single-chip mode. Table 8.6 lists CLKOUT pin function in memory expansion mode and microprocessor mode.

Table 8.5 CLKOUT Pin in Single-Chip Mode

PM0 Register ⁽¹⁾		CM0 Register ⁽²⁾		CLKOUT Pin Function
PM07 Bit		CM01 Bit	CM00 Bit	
—		0	0	P53 I/O port
1		0	1	Outputs fc
1		1	0	Outputs f8
1		1	1	Outputs f32

- : Can be set to either "0" or "1"

NOTES:

1. Rewrite the PM0 register after the PRC1 bit in the PRCR register is set to "1" (write enabled).
2. Rewrite the CM0 register after the PRC0 bit in the PRCR register is set to "1" (write enabled).

Table 8.6 CLKOUT Pin in Memory Expansion Mode and Microprocessor Mode

PM1 Register ⁽¹⁾		PM0 Register ⁽¹⁾		CM0 Register ⁽²⁾		CLKOUT Pin Function
PM15 Bit	PM14 Bit	PM07 Bit	CM01 Bit	CM00 Bit		
002, 102, 112,		0	0 ⁽³⁾	0 ⁽³⁾	0 ⁽³⁾	Outputs BCLK
		1	0	0	0	Outputs "L" (not P53)
		1	0	1	1	Outputs fc
		1	1	0	0	Outputs f8
		1	1	1	1	Outputs f32
0	1	—	0 ⁽³⁾	0 ⁽³⁾	0 ⁽³⁾	Outputs ALE

- : Can be set to either "0" or "1"

NOTES:

1. Rewrite the PM1 and PM0 registers after the PRC1 bit in the PRCR register is set to "1" (write enabled).
2. Rewrite the CM0 register after the PRC0 bit in the PRCR register is set to "1" (write enabled).
3. When the PM07 bit is set to "0" (selected in the CM01 and CM00 bits) or the PM15 and PM14 bits are set to "012" (P53/BCLK), set the CM01 and CM00 bits to "002" (I/O port P53).

8.5 Power Consumption Control

Normal operating mode, wait mode and stop mode are provided as the power consumption control. All mode states, except wait mode and stop mode, are called normal operating mode in this section. Figure 8.13 shows a block diagram of status transition in wait mode and stop mode. Figure 8.14 shows a block diagram of status transition in all modes.

8.5.1 Normal Operating Mode

The normal operating mode is further separated into six modes.

In normal operating mode, the CPU clock and peripheral function clock are supplied to operate the CPU and peripheral function. The power consumption control is enabled by controlling a CPU clock frequency. The higher the CPU clock frequency is, the more processing power increases. The lower the CPU clock frequency is, the more power consumption decreases. When unnecessary oscillation circuit stops, power consumption is further reduced.

8.5.1.1 High-Speed Mode

The main clock⁽¹⁾ becomes the CPU clock and a clock source of the peripheral function clock. When the sub clock runs, fc32 can be used as a count source for the timers A and B.

8.5.1.2 Medium-Speed Mode

The main clock⁽¹⁾ divided-by-2, -3, -4, -6, -8, -10, -12, -14, or -16 becomes the CPU clock. The main clock⁽¹⁾ is a clock source for the peripheral function clock. When the sub clock runs, fc32 can be used as a count source for the timers A and B.

8.5.1.3 Low-Speed Mode

The sub clock becomes the CPU clock. The main clock⁽¹⁾ is a clock source for the peripheral function clock. fc32 can be used as a count source for the timers A and B.

8.5.1.4 Low-Power Consumption Mode

The microcomputer enters low-power consumption mode when the main clock stops in low-speed mode. The sub clock becomes the CPU clock. Only fc32 can be used as a count source for the timers A and B and the peripheral function clock. In low-power consumption mode, the MCD4 to MCD0 bits in the MCD register are set to "010002" (divide-by-8 mode). Therefore, when the main clock resumes running, the microcomputer is in medium-speed mode (divide-by-8 mode).

8.5.1.5 On-Chip Oscillator Mode

The on-chip oscillator clock divided-by-1 (no division), -2, -3, -4, -6, -8, -10, -12, -14, or -16 becomes the CPU clock. The on-chip oscillator clock is a clock source for the peripheral function clock. When the sub clock runs, fc32 can be used as a count source for the timers A and B.

8.5.1.6 On-Chip Oscillator Low-Power Consumption Mode

The microcomputer enters on-chip oscillator low-power consumption mode when the main clock stops in on-chip oscillator mode. The on-chip oscillator clock divided-by-1 (no division), -2, -3, -4, -6, -8, -10, -12, -14, or -16 becomes the CPU clock. The on-chip oscillator clock is a clock source for the peripheral function clock. When the sub clock runs, fc32 can be used as a count source for the timers A and B.

NOTE:

1. The PLL clock, instead of the main clock, when the CM17 bit is set to "1" (PLL clock).

Switch the CPU clock after the clock to be switched to stabilize. Sub clock oscillation will take longer⁽²⁾ to stabilize. Wait, by program, until the clock stabilizes directly after turning the microcomputer on or exiting stop mode.

To switch the on-chip oscillator clock to the main clock, enter medium-speed mode (divide-by-8) after the main clock is divided by eight in on-chip oscillator mode (the MCD4 to MCD0 bits in the MCD register are set to "010002").

Do not enter on-chip oscillator mode or on-chip oscillator low-power consumption mode from low-speed mode or low-power consumption mode and vice versa.

NOTE:

2. Contact your oscillator manufacturer for oscillation stabilization time.

8.5.2 Wait Mode

In wait mode, the CPU clock stops running. The CPU and watchdog timer, operated by the CPU clock, also stop. When the PM22 bit in the PM2 register is set to "1" (on-chip oscillator clock as watchdog timer count source), the watchdog timer continues operating. Because the main clock, sub clock and on-chip oscillator clock continue running, peripheral functions using these clocks also continue operating.

8.5.2.1 Peripheral Function Clock Stop Function

If the CM02 bit in the CM0 register is set to "1" (peripheral function clock stops in wait mode), f1, f8, f32, f2n (when peripheral clock is selected as a count source), and fAD stop in wait mode. Power consumption can be reduced. f2n, when XIN clock or on-chip oscillator clock is selected as a count source, and fc32 do not stop running.

8.5.2.2 Entering Wait Mode

If wait mode is entered after setting the CM02 bit to "1", set the MCD4 to MCD0 bits in the MCD register to be the 10-MHz or less CPU clock frequency after dividing the main clock.

Enter wait mode after setting the followings.

- Initial Setting

Set each interrupt priority level after setting the exit priority level required to exit wait mode, controlled by the RLVL2 to RLVL0 bits in the RLVL register, to "7".

- Before Entering Wait Mode

- (1) Set the I flag to "0"

- (2) Set the interrupt priority level of the interrupt being used to exit wait mode

- (3) Set the interrupt priority levels of the interrupts, not being used to exit wait mode, to "0"

- (4) Set IPL in the FLG register. Then set the exit priority level to the same level as IPL

Interrupt priority level of the interrupt used to exit wait mode > IPL = the exit priority level

- (5) Set the PRC0 bit in the PRCR register to "1"

- (6) If the CPU clock source is the PLL clock, set the CM17 bit in the CM1 register to "0" (main clock) and PLC07 bit in the PLC0 register to "0" (PLL off)

- (7) Set the I flag to "1"

- (8) Execute the WAIT instruction

- After Exiting Wait Mode

Set the exit priority level to "7" as soon as exiting wait mode.

8.5.2.3 Pin Status in Wait Mode

Table 8.7 lists pin states in wait mode.

Table 8.7 Pin States in Wait Mode

Pin		Memory Expansion Mode Microprocessor Mode	Single-Chip Mode
Address Bus, Data Bus, $\overline{CS0}$ to $\overline{CS3}$, BHE		Maintains state immediately before entering wait mode	/
RD, WR, \overline{WRL} , \overline{WRH}		"H"	
HLDA, BCLK		"H"	
ALE		"L"	
Ports		Maintains state immediately before entering wait mode	
CLKOUT	When fc is selected	Outputs clock	
	When f8, f32 are selected	Outputs the clock when the CM02 bit in the CM0 register is set to "0" (peripheral function clock does not stop in wait mode). Maintains state immediately before entering wait mode when the CM02 bit is set to "1" (peripheral function clock stops in wait mode).	

8.5.2.4 Exiting Wait Mode

Wait mode is exited by the hardware reset, \overline{NMI} interrupt or peripheral function interrupts.

When the hardware reset or \overline{NMI} interrupt, but not the peripheral function interrupts, is used to exit wait mode, set the ILVL2 to ILVL0 bits for the peripheral function interrupts to "0002" (interrupt disabled) before executing the WAIT instruction.

CM02 bit setting affects the peripheral function interrupts. When the CM02 bit in the CM0 register is set to "0" (peripheral function clock does not stop in wait mode), all peripheral function interrupts can be used to exit wait mode. When the CM02 bit is set to "1" (peripheral function clock stops in wait mode), peripheral functions using the peripheral function clock stop. Therefore, the peripheral function interrupts cannot be used to exit wait mode. However, the peripheral function interrupts caused by an external clock, fc32, or f2n whose count source is the XIN clock or on-chip oscillator clock, can be used to exit wait mode.

The CPU clock used when exiting wait mode by the peripheral function interrupts or \overline{NMI} interrupt is the same CPU clock used when the WAIT instruction is executed.

Table 8.8 shows interrupts to be used to exit wait mode and usage conditions.

Table 8.8 Interrupts to Exit Wait Mode

Interrupt	When CM02=0	When CM02=1
NMI Interrupt	Available	Available
Serial I/O Interrupt	Available when the internal and external clocks are used	Available when the external clock or f_{2n} (when XIN clock or on-chip oscillator is selected) is used
Key Input Interrupt	Available	Available
A/D Conversion Interrupt	Available in single or single-sweep mode	Do not use
Timer A Interrupt Timer B Interrupt	Available in all modes	Available in event counter mode or when count source is fc_{32} or f_{2n} (when XIN clock or on-chip oscillator is selected)
\overline{INT} Interrupt	Available	Available
Intelligent I/O Interrupt	Available	Do not use

8.5.3 Stop Mode

In stop mode, all oscillators and resonators stop. The CPU clock and peripheral function clock, as well as the CPU and peripheral functions operated by these clocks, also stop. The least power required to operate the microcomputer is in stop mode. The internal RAM holds its data when the voltage applied to the VCC1 and VCC2 pins is V_{RAM} or more. If the voltage applied to the VCC1 and VCC2 pins is 2.7 V or less, the voltage must be $V_{cc1} \geq V_{cc2} \geq V_{RAM}$.

The following interrupts can be used to exit stop mode:

- \overline{NMI} interrupt
- Key Input Interrupt
- \overline{INT} interrupt
- Timer A and B interrupt (Available when the timer counts external pulse, having its 100 Hz or less frequency, in event counter mode)

8.5.3.1 Entering Stop Mode

Stop mode is entered when setting the CM10 bit in the CM1 register to "1" (all clocks stops). The MCD4 to MCD0 bits in the MCD register become set to "010002" (divide-by-8 mode).

Enter stop mode after setting the followings.

- Initial Setting

Set each interrupt priority level after setting the exit priority level required to exit stop mode, controlled by the RLVL2 to RLVL0 bits in the RLVL register, to "7".

- Before Entering stop mode

- (1) Set the I flag to "0"

- (2) Set the interrupt priority level of the interrupt being used to exit stop mode

- (3) Set the interrupt priority levels of the interrupts, not being used to exit stop mode, to "0"

- (4) Set IPL in the FLG register. Then set the exit priority level to the same level as IPL

Interrupt priority level of the interrupt used to exit stop mode > IPL = the exit priority level

- (5) Set the PRC0 bit in the PRCR register to "1" (write enabled)

- (6) Select the main clock as the CPU clock

- When the CPU clock source is the sub clock,

- (a) set the CM05 bit in the CM0 register to "0" (main clock oscillates)

- (b) set the CM07 bit in the CM0 register to "0" (clock selected by the CM21 bit divided by MCD register setting)

- When the CPU clock source is the PLL clock,

- (a) set the CM17 bit in the CM1 register to "0" (main clock)

- (b) set the PLC07 bit in the PLC0 register to "0" (PLL off)

- When the CPU clock source is the on-chip oscillator clock,

- (a) set MCD4 to MCD0 bits to "010002" (divide-by-8 mode)

- (b) set the CM05 bit to "0" (main clock oscillates)

- (c) set the CM21 bit in the CM2 register to "0" (clock selected by the CM17 bit)

- (7) The oscillation stop detect function is used, set the CM20 bit in the CM2 register to "0" (oscillation stop detect function disabled)

- (8) Set the I flag to "1"

- (9) Set the CM10 bit to "1" (all clocks stops)

- After Exiting Stop Mode

Set the exit priority level to "7" as soon as exiting stop mode.

8.5.3.2 Exiting Stop Mode

Stop mode is exited by the hardware reset, $\overline{\text{NMI}}$ interrupt or peripheral function interrupts (key input interrupt and $\overline{\text{INT}}$ interrupt).

When the hardware reset or $\overline{\text{NMI}}$ interrupt, but not the peripheral function interrupts, is used to exit wait mode, set all ILVL2 to ILVL0 bits in the interrupt control registers for the peripheral function interrupt to "0002" (interrupt disabled) before setting the CM10 bit to "1" (all clocks stops).

8.5.3.3 Pin Status in Stop Mode

Table 8.9 lists pin status in stop mode.

Table 8.9 Pin Status in Stop Mode

Pin		Memory Expansion Mode Microprocessor Mode	Single-Chip Mode
Address Bus, Data Bus, $\overline{CS0}$ to $\overline{CS3}$, \overline{BHE}		Maintains state immediately before entering stop mode	/
\overline{RD} , \overline{WR} , \overline{WRL} , \overline{WRH}		"H"	
\overline{HLDA} , \overline{BCLK}		"H"	
ALE		"H"	
Ports		Maintains state immediately before entering stop mode	
CLKOUT	When f _c selected	"H"	
	When f ₈ , f ₃₂ selected	Maintains state immediately before entering stop mode	
XIN		Placed in a high-impedance state	
XOUT		"H"	
XCIN, XCOUT		Placed in a high-impedance state	

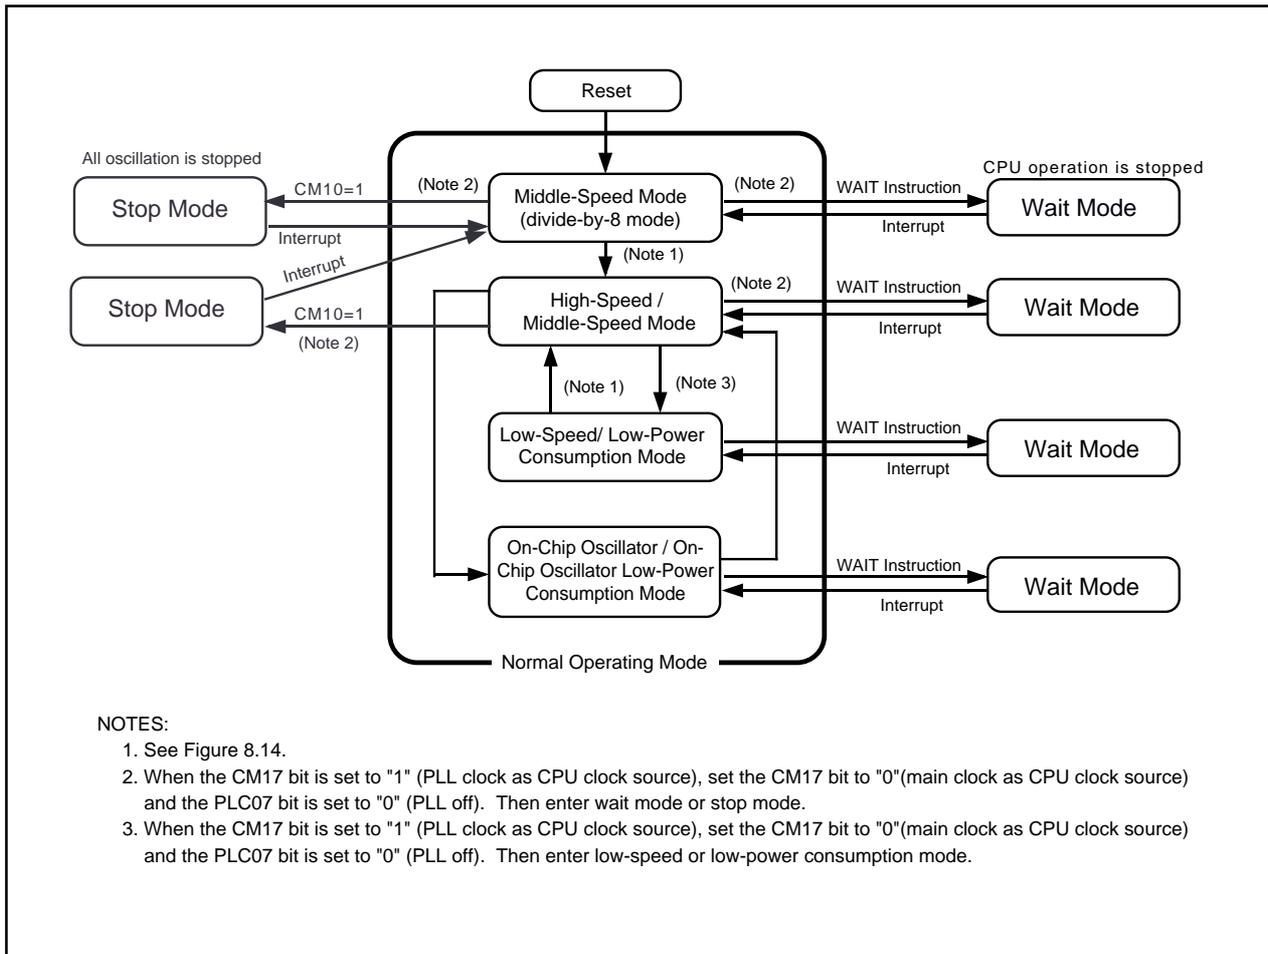

Figure 8.13 Status Transition in Wait Mode and Stop Mode

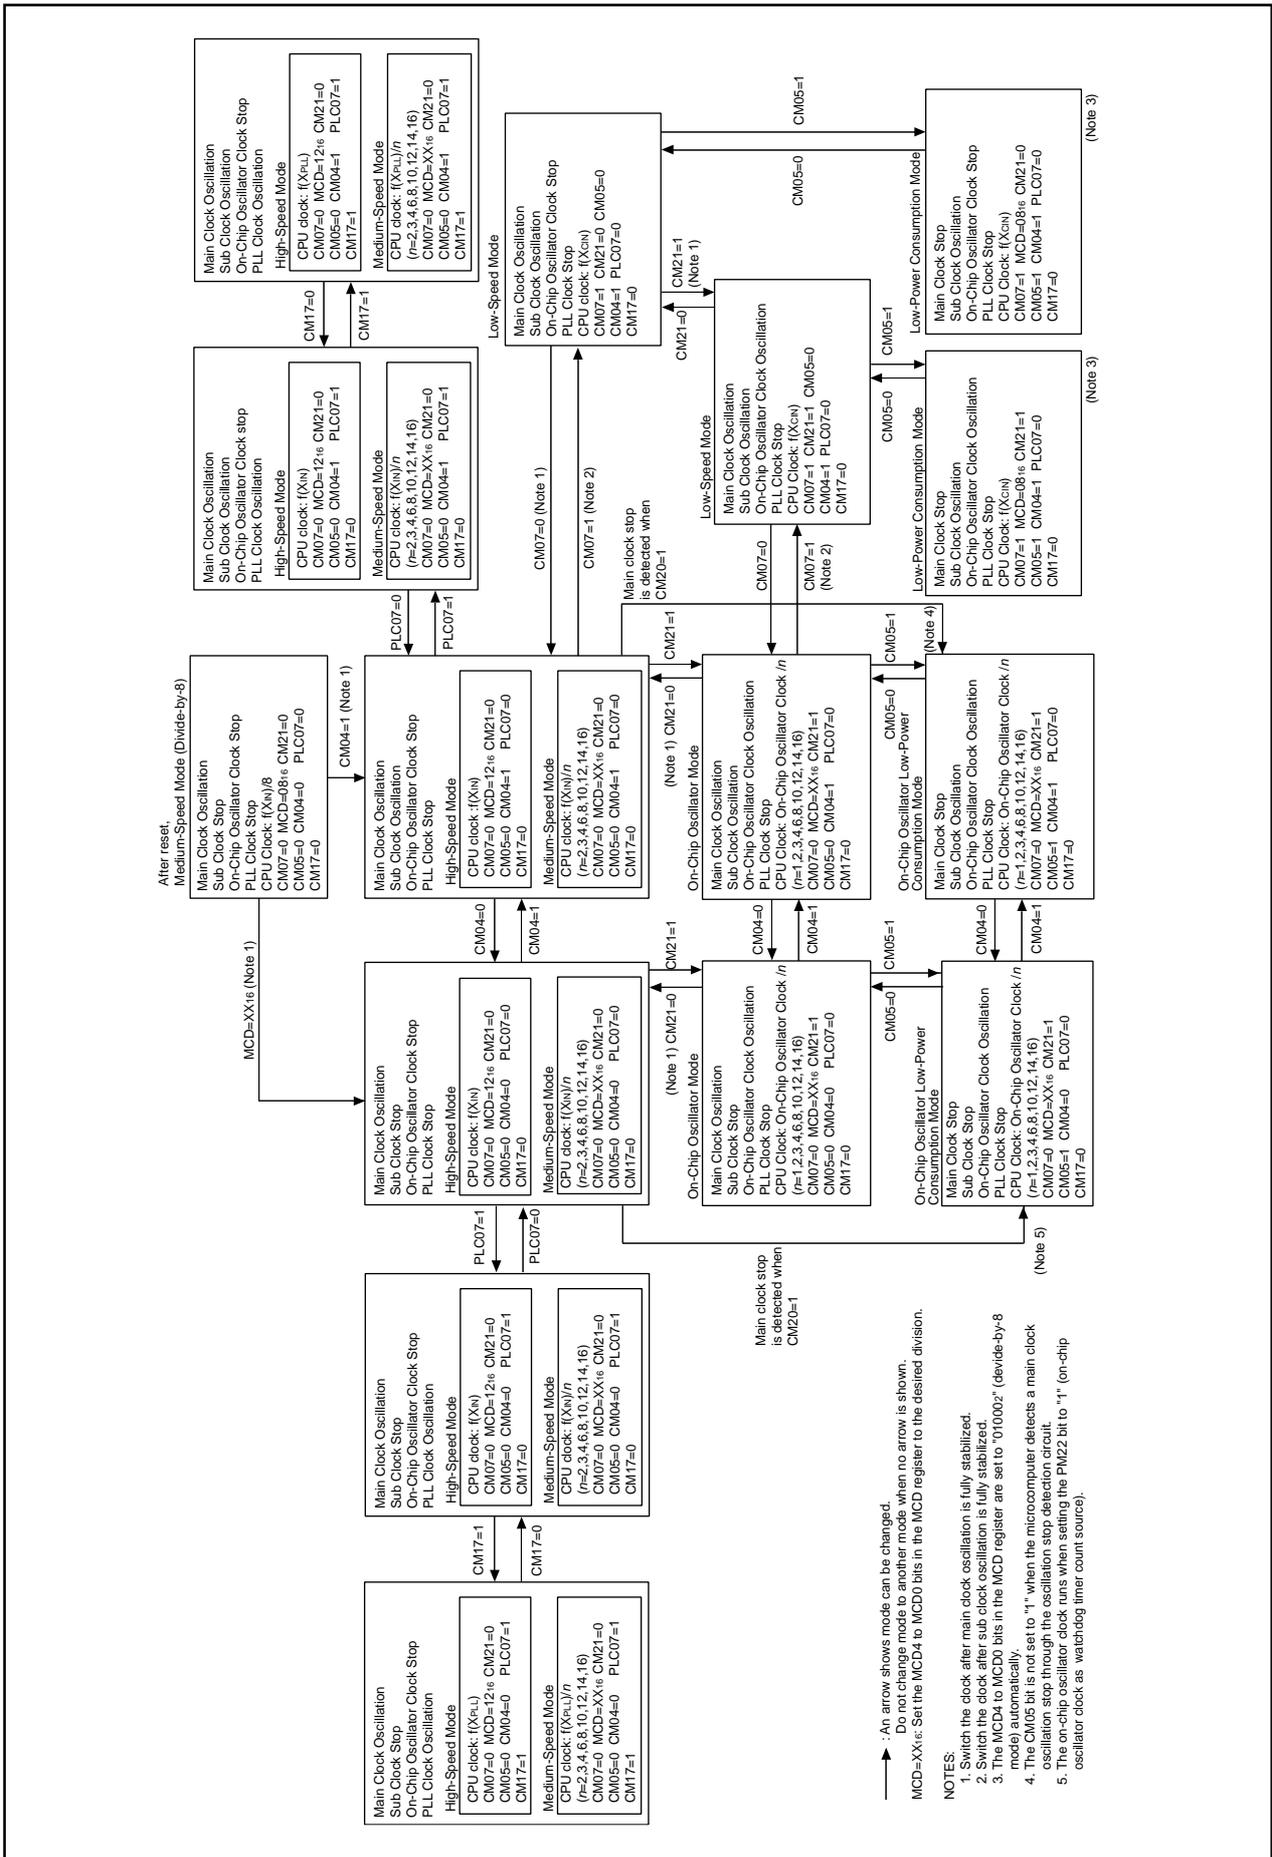

Figure 8.14 Status Transition

8.6 System Clock Protect Function

The system clock protect function prohibits the CPU clock from changing clock sources when the main clock is selected as the CPU clock source. This prevents the CPU clock from stopping the program crash. When the PM21 bit in the PM2 register is set to "1" (clock change disabled), the following bits cannot be written to:

- The CM02 bit, CM05 bit and CM07 bit in the CM0 register
- The CM10 bit and CM17 bit in the CM1 register
- The CM20 bit in the CM2 register
- All bits in the PLC0 and PLC1 registers

The CPU clock continues running when the WAIT instruction is executed.

To use the system clock protect function, set the CM05 bit in the CM0 register to "0" (main clock oscillation) and CM07 bit to "0" (main clock as BCLK clock source) and follow the procedure below.

- (1) Set the PRC1 bit in the PRCR register to "1" (write enabled).
- (2) Set the PM21 bit in the PM2 register to "1" (protects the clock).
- (3) Set the PRC1 bit in the PRCR register to "0" (write disabled).

When the PM21 bit is set to "1", do not execute the WAIT instruction.

9. Protection

The protection function protects important registers from being easily overwritten when a program runs out of control.

Figure 9.1 shows the PRCR register. Each bit in the PRCR register protects the following registers:

- The PRC0 bit protects the CM0, CM1, CM2, MCD, PLC0 and PLC1 registers;
- The PRC1 bit protects the PM0, PM1, PM2, INVC0 and INVC1 registers;
- The PRC2 bit protects the PD9 and PS3 registers;

The PRC2 bit is set to "0" (write disabled) when data is written to a desired address after setting the PRC2 bit to "1" (write enabled). Set the PD9 and PS3 registers immediately after setting the PRC2 bit in the PRCR register to "1" (write enabled). Do not generate an interrupt or a DMA transfer between the instruction to set the PRC2 bit to "1" and the following instruction. The PRC1 and PRC0 bits are not set to "0" even if data is written to desired addresses. Set the PRC1 and PRC0 bits to "0" by program.

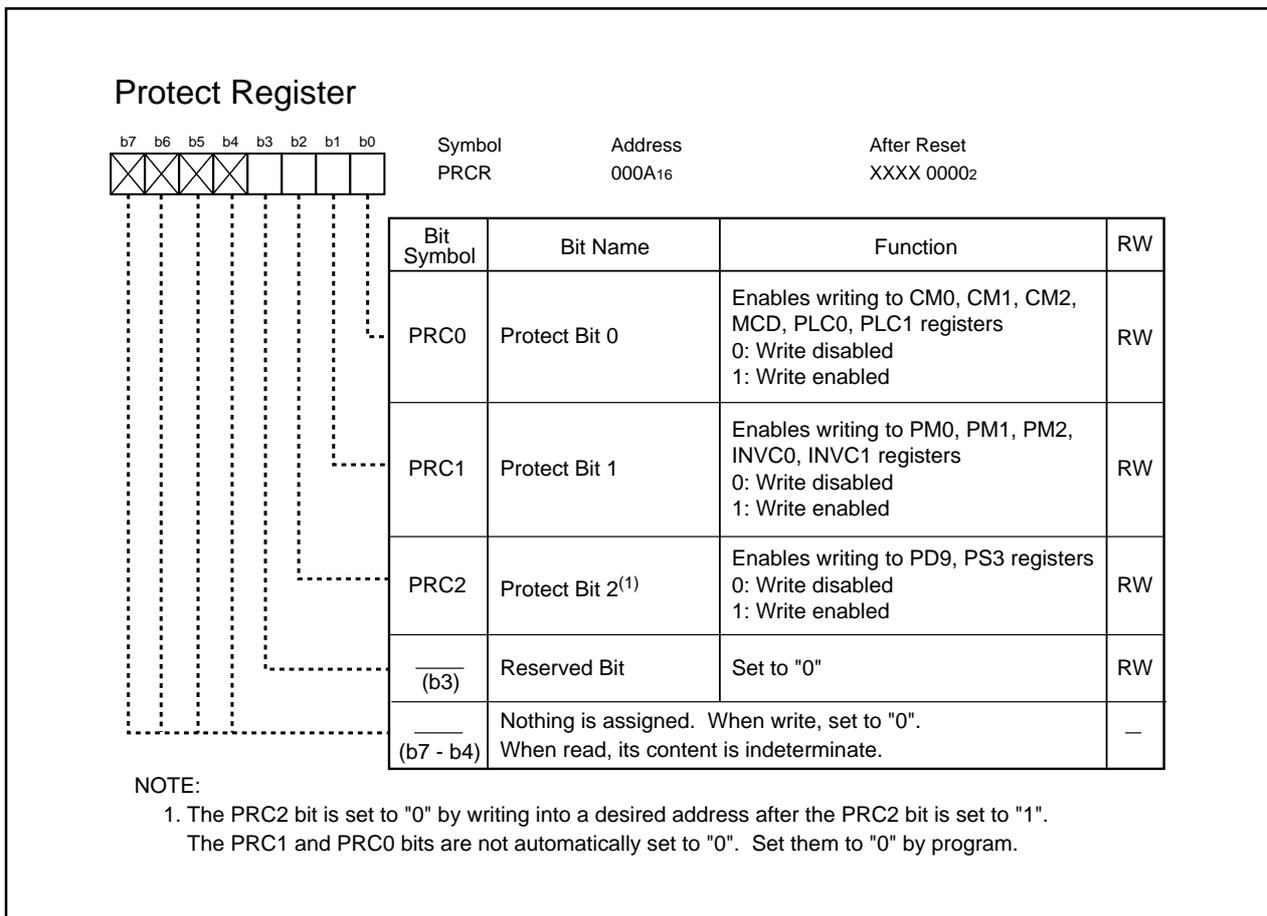

Figure 9.1 PRCR Register

10. Interrupts

10.1 Types of Interrupts

Figure 10.1 shows types of interrupts.

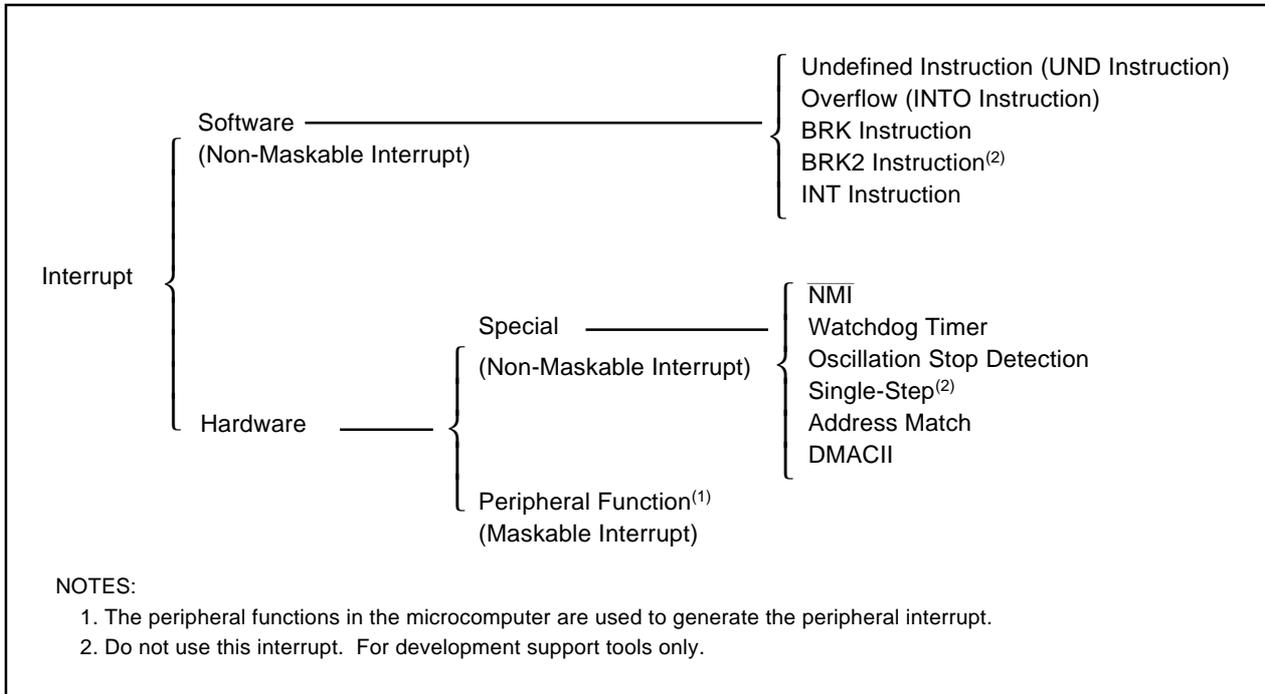

Figure 10.1 Interrupts

- Maskable Interrupt

The I flag enables or disables an interrupt.

The interrupt priority order based on interrupt priority level **can be changed**.

- Non-Maskable Interrupt

The I flag does not enable nor disable an interrupt .

The interrupt priority order based on interrupt priority level **cannot be changed**.

10.2 Software Interrupts

Software interrupt occurs when an instruction is executed. The software interrupts are non-maskable interrupts.

10.2.1 Undefined Instruction Interrupt

The undefined instruction interrupt occurs when the UND instruction is executed.

10.2.2 Overflow Interrupt

The overflow interrupt occurs when the O flag in the FLG register is set to "1" (overflow of arithmetic operation) and the INTO instruction is executed.

Instructions to set the O flag are :

ABS, ADC, ADCF, ADD, ADDX, CMP, CMPX, DIV, DIVU, DIVX, NEG, RMPA, SBB, SCMPU, SHA, SUB, SUBX

10.2.3 BRK Interrupt

The BRK interrupt occurs when the BRK instruction is executed.

10.2.4 BRK2 Interrupt

The BRK2 interrupt occurs when the BRK2 instruction is executed.

Do not use this interrupt. For development support tools only.

10.2.5 INT Instruction Interrupt

The INT instruction interrupt occurs when the INT instruction is executed. The INT instruction can select software interrupt numbers 0 to 63. Software interrupt numbers 8 to 48 are assigned to the vector table used for the peripheral function interrupt. Therefore, the microcomputer executes the same interrupt routine when the INT instruction is executed as when a peripheral function interrupt occurs.

When the INT instruction is executed, the FLG register and PC are saved to the stack. PC also stores the relocatable vector of specified software interrupt numbers. Where the stack is saved varies depending on a software interrupt number. ISP is selected as the stack for software interrupt numbers 0 to 31 (setting the U flag to "0"). SP, which is set before the INT instruction is executed, is selected as the stack for software interrupt numbers 32 to 63 (the U flag is not changed).

With the peripheral function interrupt, the FLG register is saved and the U flag is set to "0" (ISP select) when an interrupt request is acknowledged. With software interrupt numbers 32 to 48, SP to be used varies depending on whether the interrupt is generated by the peripheral function interrupt request or by the INT instruction.

10.3 Hardware Interrupts

Special interrupts and peripheral function interrupts are available as hardware interrupts.

10.3.1 Special Interrupts

Special interrupts are non-maskable interrupts.

10.3.1.1 $\overline{\text{NMI}}$ Interrupt

The $\overline{\text{NMI}}$ interrupt occurs when a signal applied to the $\overline{\text{NMI}}$ pin changes from a high-level ("H") signal to a low-level ("L") signal. Refer to **10.8 NMI Interrupt** for details.

10.3.1.2 Watchdog Timer Interrupt

The watchdog timer interrupt occurs when a count source of the watchdog timer underflows. Refer to **11. Watchdog Timer** for details.

10.3.1.3 Oscillation Stop Detection Interrupt

The oscillation stop detection interrupt occurs when the microcomputer detects a main clock oscillation stop. Refer to **8. Clock Generation Circuit** for details.

10.3.1.4 Single-Step Interrupt

Do not use the single-step interrupt. For development support tool only.

10.3.1.5 Address Match Interrupt

The address match interrupt occurs immediately before executing an instruction that is stored into an address indicated by the RMADi register (i=0 to 7) when the AIERi bit in the AIER register is set to "1" (address match interrupt enabled). Set the starting address of the instruction in the RMADi register. The address match interrupt does not occur when a table data or addresses of the instruction other than the starting address, if the instruction has multiple addresses, is set. Refer to **10.10 Address Match Interrupt** for details.

10.3.2 Peripheral Function Interrupt

The peripheral function interrupt occurs when a request from the peripheral functions in the microcomputer is acknowledged. The peripheral function interrupts and software interrupt numbers 8 to 48 for the INT instruction use the same interrupt vector table. The peripheral function interrupt is a maskable interrupt.

See **Table 10.2** about how the peripheral function interrupt occurs. Refer to the descriptions of each function for details.

10.4 High-Speed Interrupt

The high-speed interrupt executes an interrupt sequence in five cycles and returns from the interrupt in three cycles.

When the FSIT bit in the RLVL register is set to "1" (interrupt priority level 7 available for the high-speed interrupt), the ILVL2 to ILVL0 bits in the interrupt control registers can be set to "1112" (level 7) to use the high-speed interrupt.

Only one interrupt can be set as the high-speed interrupt. When using the high-speed interrupt, do not set multiple interrupts to interrupt priority level 7. Set the DMAII bit in the RLVL register to "0" (interrupt priority level 7 available for interrupts).

Set the starting address of the high-speed interrupt routine in the VCT register.

When the high-speed interrupt is acknowledged, the FLG register is saved into the SVF register and PC is saved into the SVP register. The program is executed from an address indicated by the VCT register.

Execute the FREIT instruction to return from the high-speed interrupt routine.

The values saved into the SVF and SVP registers are restored to the FLG register and PC by executing the FREIT instruction.

The high-speed interrupt and the DMA2 and DMA3 use the same register. When using the high-speed interrupt, neither DMA2 nor DMA3 is available. DMA0 and DMA1 can be used.

10.5 Interrupts and Interrupt Vectors

There are four bytes in one vector. Set the starting address of interrupt routine in each vector table. When an interrupt request is acknowledged, the interrupt routine is executed from the address set in the interrupt vectors.

Figure 10.2 shows the interrupt vector.

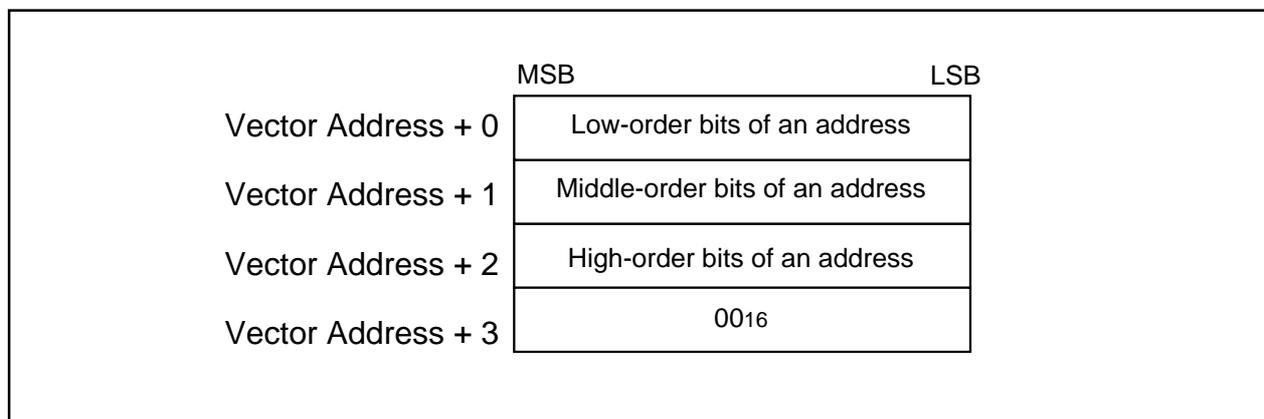

Figure 10.2 Interrupt Vector

10.5.1 Fixed Vector Tables

The fixed vector tables are allocated addresses FFFFDC₁₆ to FFFFFFF₁₆. Table 10.1 lists the fixed vector tables.

Table 10.1 Fixed Vector Table

Interrupt Generated by	Vector Addresses Low address to High address	Remarks	Reference
Undefined Instruction	FFFFDC ₁₆ to FFFFDF ₁₆		M32C/80 Series Software Manual
Overflow	FFFFE0 ₁₆ to FFFFFE3 ₁₆		
BRK Instruction	FFFFE4 ₁₆ to FFFFFE7 ₁₆	If the content of address FFFFFE7 ₁₆ is FF ₁₆ , a program is executed from the address stored into software interrupt number 0 in the relocatable vector table	
Address Match	FFFFE8 ₁₆ to FFFFFEB ₁₆		
-	FFFFEC ₁₆ to FFFFFEF ₁₆	Reserved space	
Watchdog Timer	FFFFF0 ₁₆ to FFFFFF3 ₁₆	These addresses are used for the watchdog timer interrupt and oscillation stop detection interrupt	Reset, Clock Generation Circuit, Watchdog Timer
-	FFFFF4 ₁₆ to FFFFFF7 ₁₆	Reserved space	
NMI	FFFFF8 ₁₆ to FFFFFFB ₁₆		
Reset	FFFFFC ₁₆ to FFFFFFF ₁₆		Reset

10.5.2 Relocatable Vector Tables

The relocatable vector tables occupy 256 bytes from the starting address set in the INTB register. Table 10.2 lists the relocatable vector tables.

Set an even address as the starting address of the vector table set in the INTB register to increase interrupt sequence execution rate.

Table 10.2 Relocatable Vector Tables

Interrupt Generated by	Vector Table Address Address(L) to Address(H) ⁽¹⁾	Software Interrupt Number	Reference
BRK Instruction ⁽²⁾	+0 to +3 (0000 ₁₆ to 0003 ₁₆)	0	M32C/80 Series
Reserved Space	+4 to +31 (0004 ₁₆ to 001F ₁₆)	1 to 7	Software Manual

NOTES:

1. These addresses are relative to those in the INTB register.
2. The I flag does not disable interrupts.
3. In I²C mode, NACK, ACK or start/stop condition detection causes interrupts to be generated.
4. The IFSR6 bit in the IFSR register determines whether these addresses are used for an interrupt in UART0 or in UART3.
The IFSR7 bit in the IFSR register determines whether these addresses are used for an interrupt in UART1 or in UART4.

10.6 Interrupt Request Acknowledgement

Software interrupts and special interrupts occur when conditions to generate an interrupt are met.

The peripheral function interrupts are acknowledged when all conditions below are met.

- I flag = "1"
- IR bit = "1"
- ILVL2 to ILVL0 bits > IPL

The I flag, IPL, IR bit and ILVL2 to ILVL0 bits are independent of each other. The I flag and IPL are in the FLG register. The IR bit and ILVL2 to ILVL0 bits are in the interrupt control register.

10.6.1 I Flag and IPL

The I flag enables or disables maskable interrupts. When the I flag is set to "1" (enable), all maskable interrupts are enabled; when the I flag is set to "0" (disable), they are disabled. The I flag is automatically set to "0" after reset.

IPL, consisting of three bits, indicates the interrupt priority level from level 0 to level 7.

If a requested interrupt has higher priority level than indicated by IPL, the interrupt is acknowledged.

Table 10.3 lists interrupt priority levels associated with IPL.

Table 10.3 Interrupt Priority Levels

IPL2	IPL1	IPL0	Interrupt Priority Levels
0	0	0	Level 1 and above
0	0	1	Level 2 and above
0	1	0	Level 3 and above
0	1	1	Level 4 and above
1	0	0	Level 5 and above
1	0	1	Level 6 and above
1	1	0	Level 7 and above
1	1	1	All maskable interrupts are disabled

10.6.2 Interrupt Control Register and RLVL Register

The peripheral function interrupts use interrupt control registers to control each interrupt. Figures 10.3 and 10.4 show the interrupt control register. Figure 10.5 shows the RLVL register.

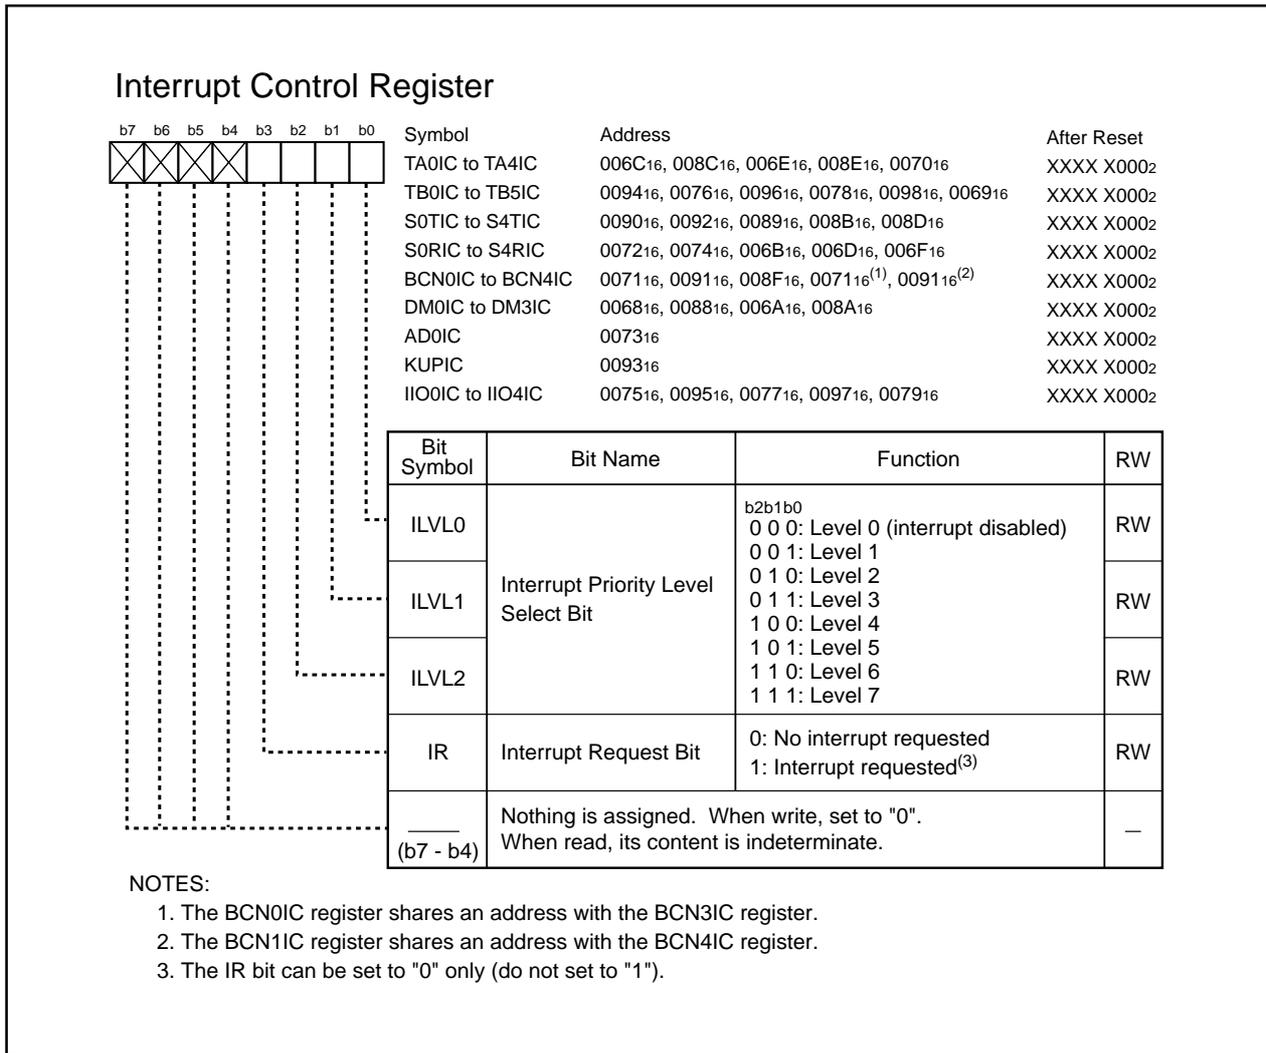

Figure 10.3 Interrupt Control Register (1)

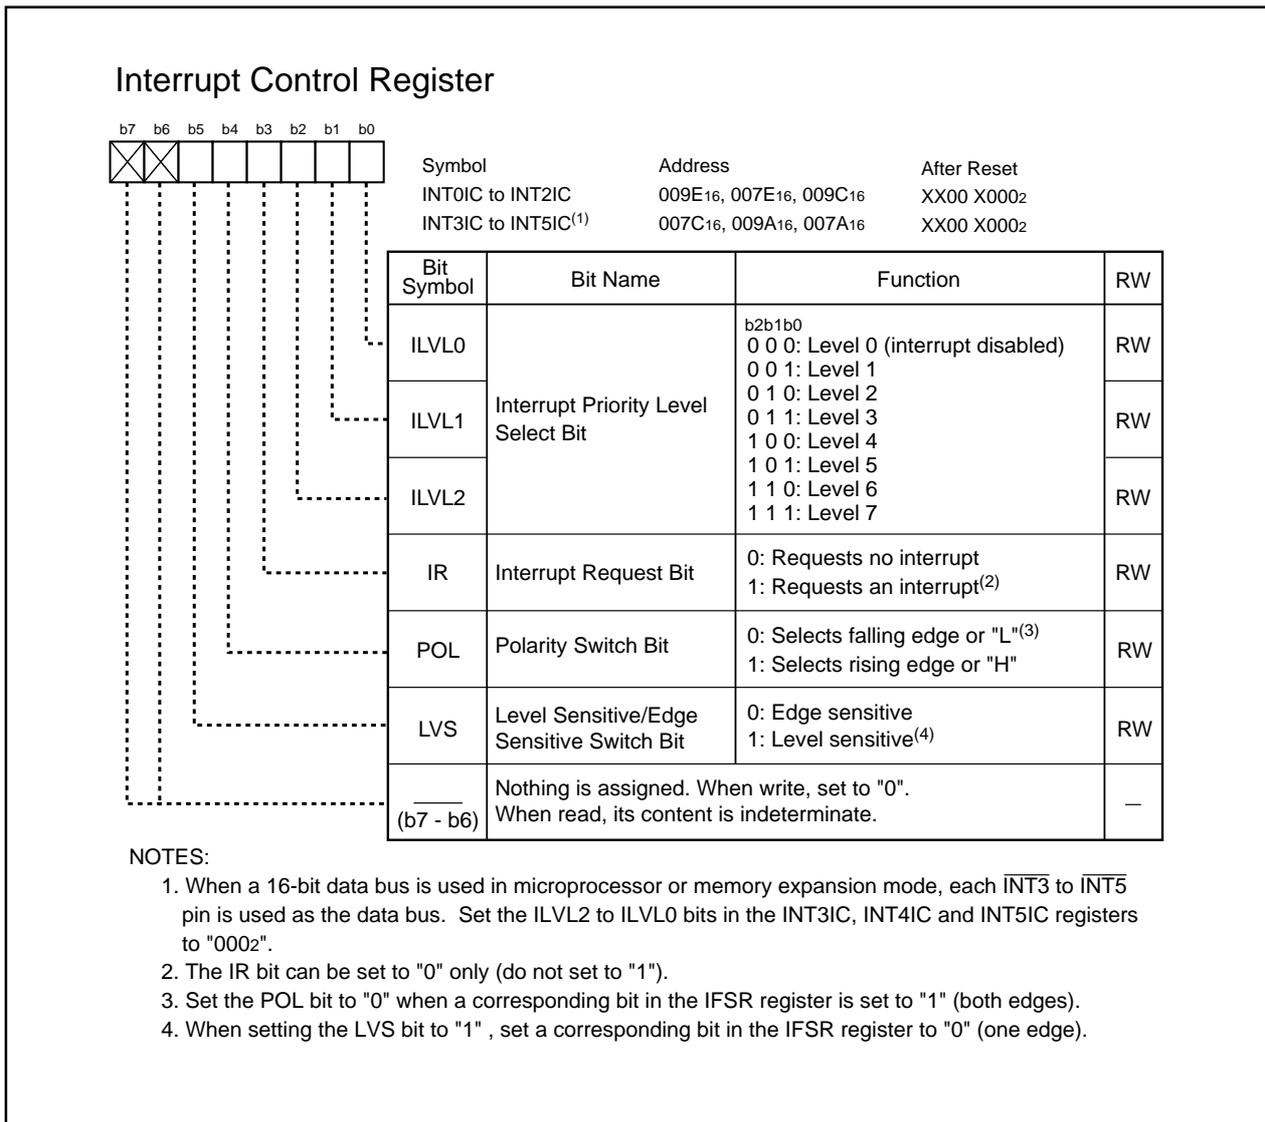

Figure 10.4 Interrupt Control Register (2)

10.6.2.1 ILVL2 to ILVL0 Bits

The ILVL2 to ILVL0 bits determines an interrupt priority level. The higher the interrupt priority level is, the higher interrupt priority is.

When an interrupt request is generated, its interrupt priority level is compared to IPL. This interrupt is acknowledged only when its interrupt priority level is higher than IPL. When the ILVL2 to ILVL0 bits are set to "0002" (level 0), its interrupt is ignored.

10.6.2.2 IR Bit

The IR bit is automatically set to "1" (interrupt requested) when an interrupt request is generated. The IR bit is automatically set to "0" (no interrupt requested) after an interrupt request is acknowledged and an interrupt routine in the corresponding interrupt vector is executed.

The IR bit can be set to "0" by program. Do not set to "1".

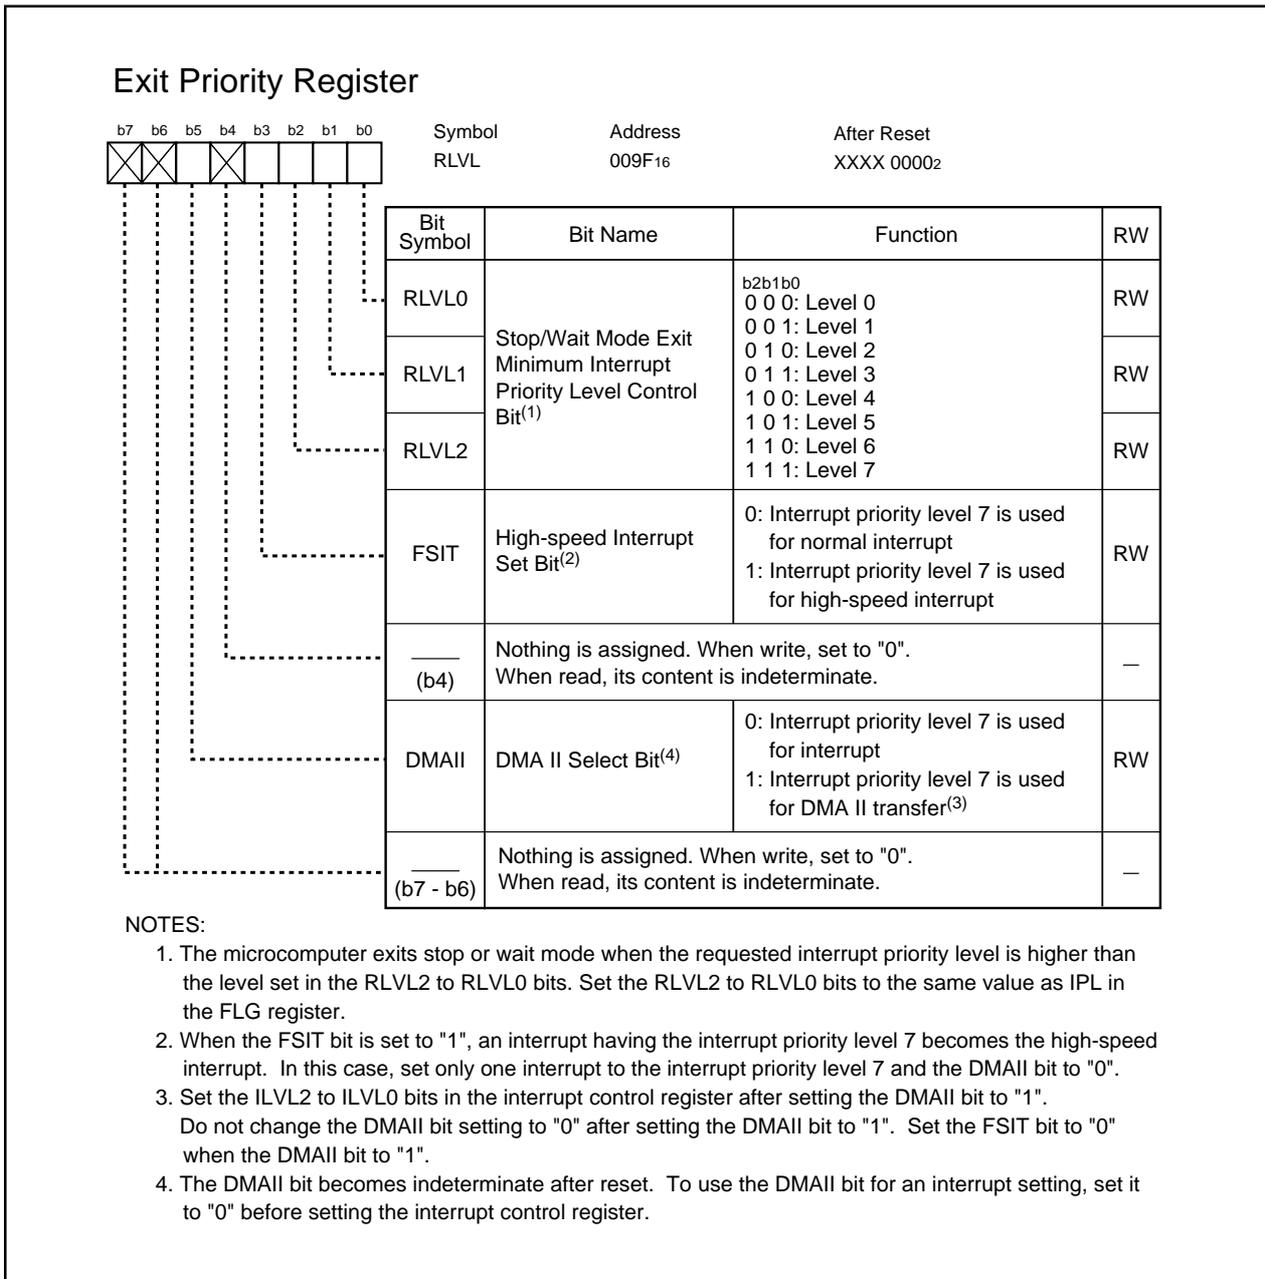

Figure 10.5 RLVL Register

10.6.2.3 RLVL2 to RLVL0 Bits

When using an interrupt to exit stop or wait mode, refer to **8.5.2 Wait Mode** and **8.5.3 Stop Mode** for details.

10.6.3 Interrupt Sequence

The interrupt sequence is performed between an interrupt request acknowledgment and interrupt routine execution.

When an interrupt request is generated while an instruction is executed, the CPU determines its interrupt priority level after the instruction is completed. The CPU starts the interrupt sequence from the following cycle. However, in regards to the SCMPU, SIN, SMOVB, SMOVF, SMOVU, SSTR, SOUT or RMPA instruction, if an interrupt request is generated while executing the instruction, the microcomputer suspends the instruction to start the interrupt sequence.

The interrupt sequence is performed as follows:

- (1) The CPU obtains interrupt information (interrupt number and interrupt request level) by reading address 000000₁₆ (address 000002₁₆ for the high-speed interrupt). Then, the IR bit applicable to the interrupt information is set to "0" (interrupt requested).
- (2) The FLG register, prior to an interrupt sequence, is saved to a temporary register⁽¹⁾ within the CPU.
- (3) Each bit in the FLG register is set as follows:
 - The I flag is set to "0" (interrupt disabled)
 - The D flag is set to "0" (single-step disabled)
 - The U flag is set to "0" (ISP selected)
- (4) A temporary register within the CPU is saved to the stack; or to the SVF register for the high-speed interrupt.
- (5) PC is saved to the stack; or to the SVP register for the high-speed interrupt.
- (6) The interrupt priority level of the acknowledged interrupt is set in IPL .
- (7) A relocatable vector corresponding to the acknowledged interrupt is stored into PC.

After the interrupt sequence is completed, an instruction is executed from the starting address of the interrupt routine.

NOTE:

1. Temporary register cannot be modified by users.

10.6.4 Interrupt Response Time

Figure 10.6 shows an interrupt response time. Interrupt response time is the period between an interrupt generation and the execution of the first instruction in an interrupt routine. Interrupt response time includes the period between an interrupt request generation and the completed execution of an instruction ((a) on Figure 10.6) and the period required to perform an interrupt sequence ((b) on Figure 10.6).

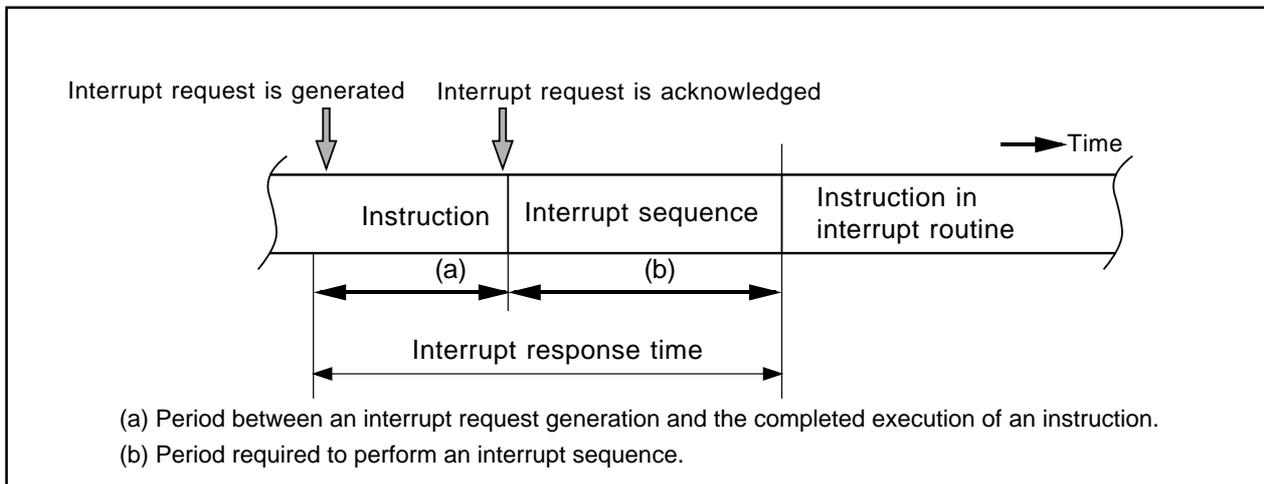

Figure 10.6 Interrupt Response Time

Time (a) varies depending on an instruction being executed. The DIV, DIVX and DIVU instructions require the longest time (a); 42 cycles when an immediate value or register is set as the divisor. When the divisor is a value in the memory, the following value is added.

- Normal addressing : $2 + X$
- Index addressing : $3 + X$
- Indirect addressing : $5 + X + 2Y$
- Indirect index addressing : $6 + X + 2Y$

X is the number of wait states for a divisor space. Y is the number of wait states for the space that stores indirect addresses. If X and Y are in an odd address or in 8-bit bus space, the X and Y value must be doubled.

Table 10.4 lists time (b), shown Figure 10.6.

Table 10.4 Interrupt Sequence Execution Time

Interrupt	Interrupt Vector Address	16-Bit Bus	8-Bit Bus
Peripheral Function	Even address	14 cycles	16 cycles
	Odd address ⁽¹⁾	16 cycles	16 cycles
INT Instruction	Even address	12 cycles	14 cycles
	Odd address ⁽¹⁾	14 cycles	14 cycles
NMI Watchdog Timer Undefined Instruction Address Match	Even address ⁽²⁾	13 cycles	15 cycles
Overflow	Even address ⁽²⁾	14 cycles	16 cycles
BRK Instruction (relocatable vector table)	Even address	17 cycles	19 cycles
	Odd address ⁽¹⁾	19 cycles	19 cycles
BRK Instruction (fixed vector table)	Even address ⁽²⁾	19 cycles	21 cycles
High-speed Interrupt	Vector table is internal register	5 cycles	

NOTES:

1. Allocate interrupt vectors in even addresses.
2. Vectors are fixed to even addresses.

10.6.5 IPL Change when Interrupt Request is Acknowledged

When a peripheral function interrupt request is acknowledged, IPL sets the priority level for the acknowledged interrupt.

Software interrupts and special interrupts have no interrupt priority level. If an interrupt request that has no interrupt priority level is acknowledged, the value shown in Table 10.5 is set in IPL as the interrupt priority level.

Table 10.5 Interrupts without Interrupt Priority Levels and IPL

Interrupt Source	Level Set to IPL
Watchdog Timer, NMI, Oscillation Stop Detection	7
Reset	0
Software, Address Match	Not changed

10.6.6 Saving a Register

In the interrupt sequence, the FLG register and PC are saved to the stack.

After the FLG register is saved to the stack, 16 high-order bits and 16 low-order bits of PC, extended to 32 bits, are saved to the stack. Figure 10.7 shows stack states before and after an interrupt request is acknowledged.

Other important registers are saved by program at the beginning of an interrupt routine. The PUSHM instruction can save several registers⁽¹⁾ in the register bank used.

Refer to **10.4 High-Speed Interrupt** for the high-speed interrupt.

NOTE:

1. Can be selected from the R0, R1, R2, R3, A0, A1, SB and FB registers.

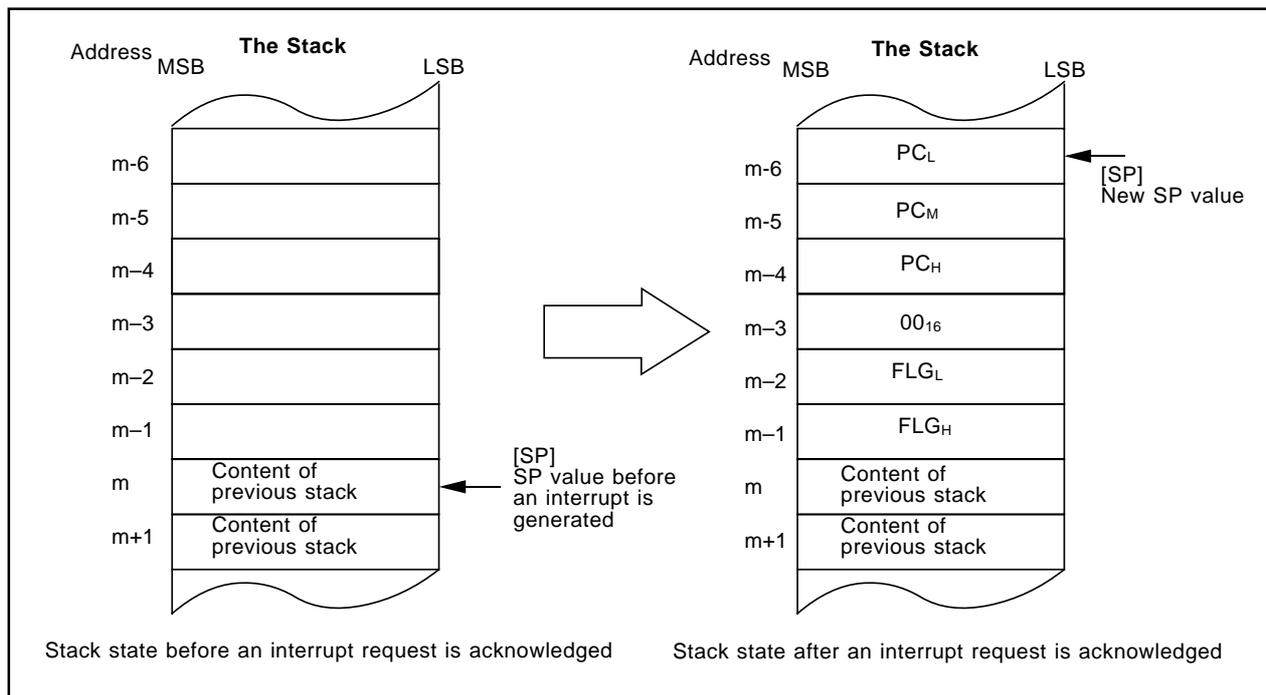

Figure 10.7 Stack States

10.6.7 Restoration from Interrupt Routine

When the REIT instruction is executed at the end of an interrupt routine, the FLG register and PC before the interrupt sequence is performed, which have been saved to the stack, are automatically restored. The program, executed before an interrupt request was acknowledged, starts running again. Refer to **10.4 High-Speed Interrupt** for the high-speed interrupt.

Restore registers saved by program in an interrupt routine by the POPM instruction or others before the REIT and FREIT instructions. Register bank is switched back to the bank used prior to the interrupt sequence by the REIT or FREIT instruction.

10.6.8 Interrupt Priority

If two or more interrupt requests are sampled at the same sampling points (a timing to detect whether an interrupt request is generated or not), the interrupt with the highest priority is acknowledged.

Set the ILVL2 to ILVL0 bits to select the desired priority level for maskable interrupts (peripheral function interrupt).

Priority levels of special interrupts such as reset (reset has the highest priority) and watchdog timer are set by hardware. Figure 10.8 shows priority levels of hardware interrupts.

The interrupt priority does not affect software interrupts. Executing instruction causes the microcomputer to execute an interrupt routine.

Reset > $\overline{\text{NMI}}$ > Oscillation Stop Detection > Peripheral Function > Address Match Watchdog

Figure 10.8 Interrupt Priority

10.6.9 Interrupt Priority Level Select Circuit

The interrupt priority level select circuit selects the highest priority interrupt when two or more interrupt requests are sampled at the same sampling point.

Figure 10.9 shows the interrupt priority level select circuit.

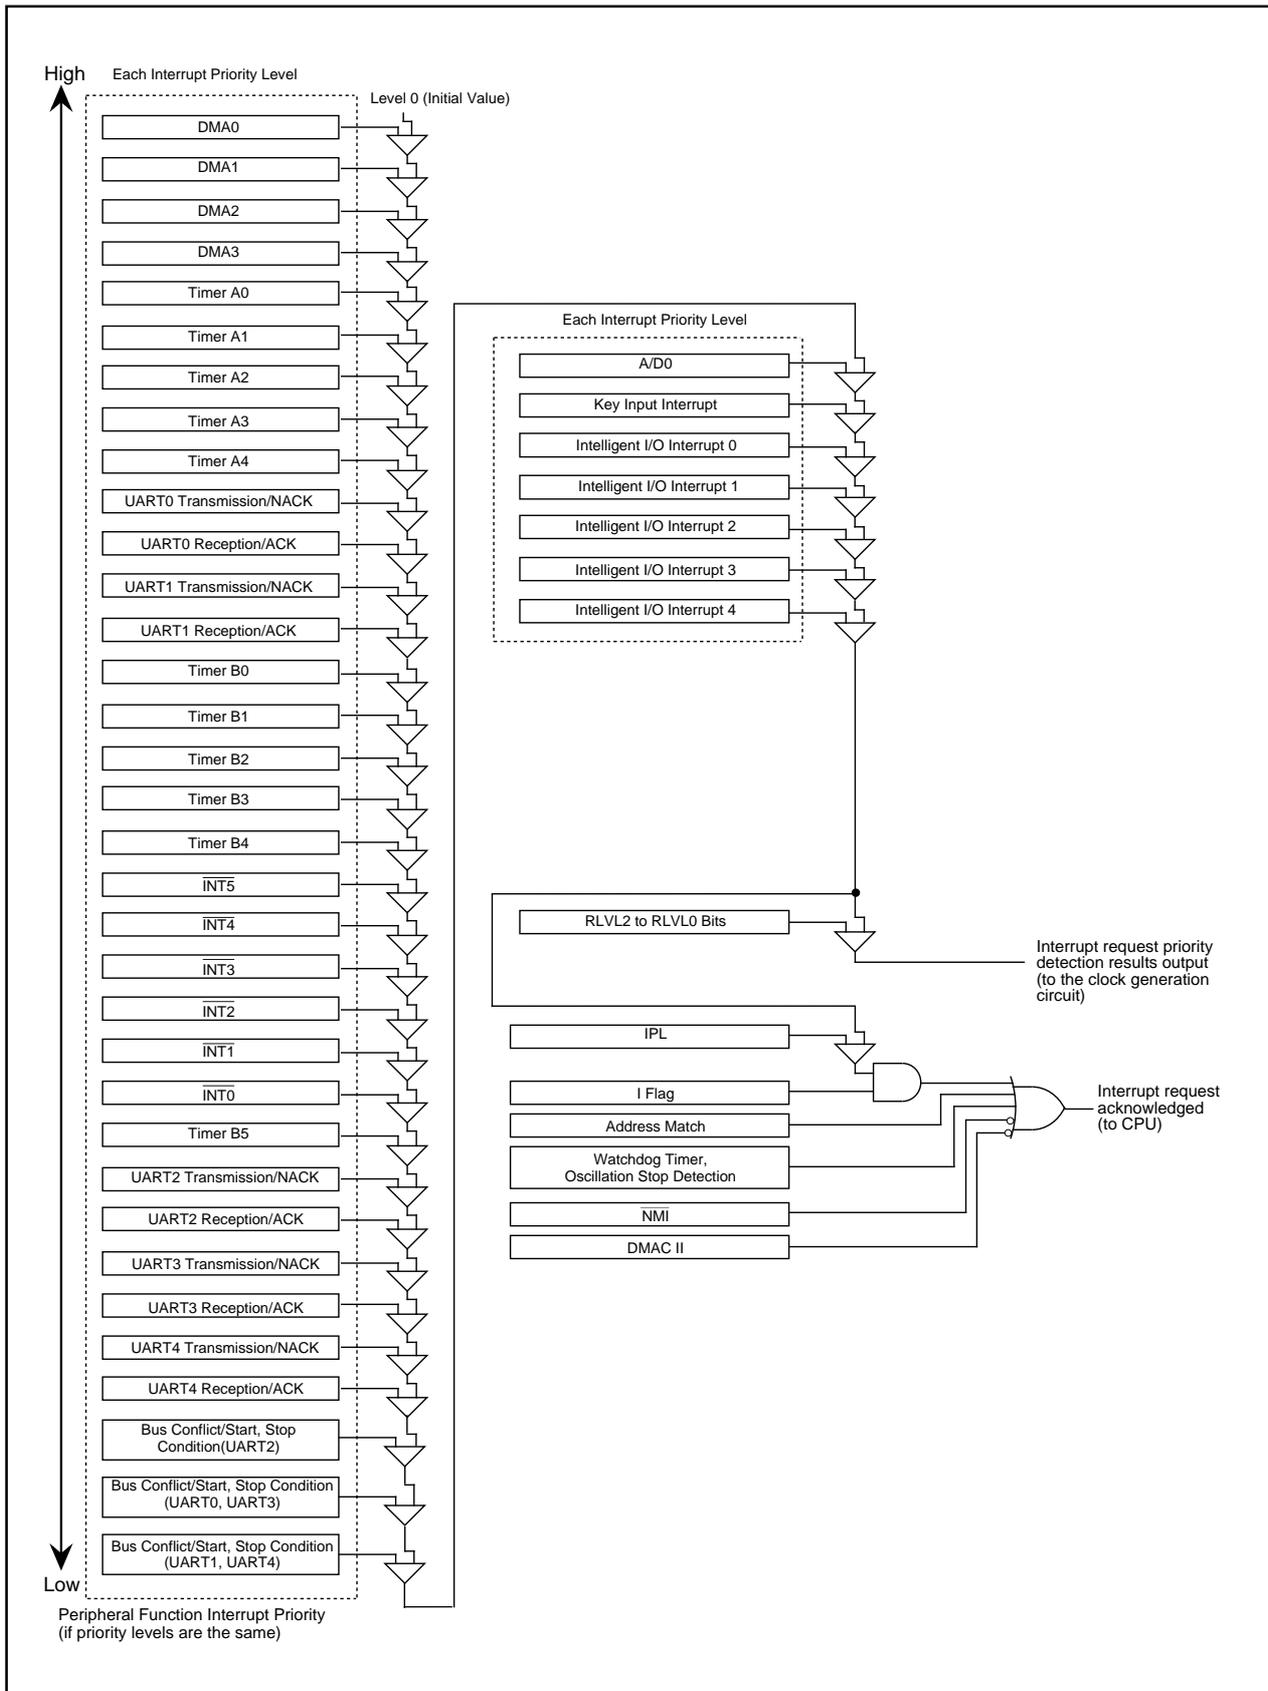

Figure 10.9 Interrupt Priority Level Select Circuit

10.7 $\overline{\text{INT}}$ Interrupt

External input generates the $\overline{\text{INT}}_i$ interrupt ($i = 0$ to 5). The LVS bit in the INTiIC register selects either edge sensitive triggering to generate an interrupt on any edge or level sensitive triggering to generate an interrupt at an applied signal level. The POL bit in the INTiIC register determines the polarity.

For edge sensitive, when the IFSR_i bit in the IFSR register is set to "1", an interrupt occurs on both rising and falling edges of the external input. If the IFSR_i bit is set to "1", set the POL bit in the corresponding register to "0" (falling edge).

For level sensitive, set the IFSR_i bit to "0" (single edge). When the $\overline{\text{INT}}_i$ pin input level reaches the level set in the POL bit, the IR bit in the INTiIC register is set to "1". The IR bit remains unchanged even if the $\overline{\text{INT}}_i$ pin level is changed. The IR bit is set to "0" when the $\overline{\text{INT}}_i$ interrupt is acknowledged or when the IR bit is written to "0" by program.

Figure 10.10 shows the IFSR register.

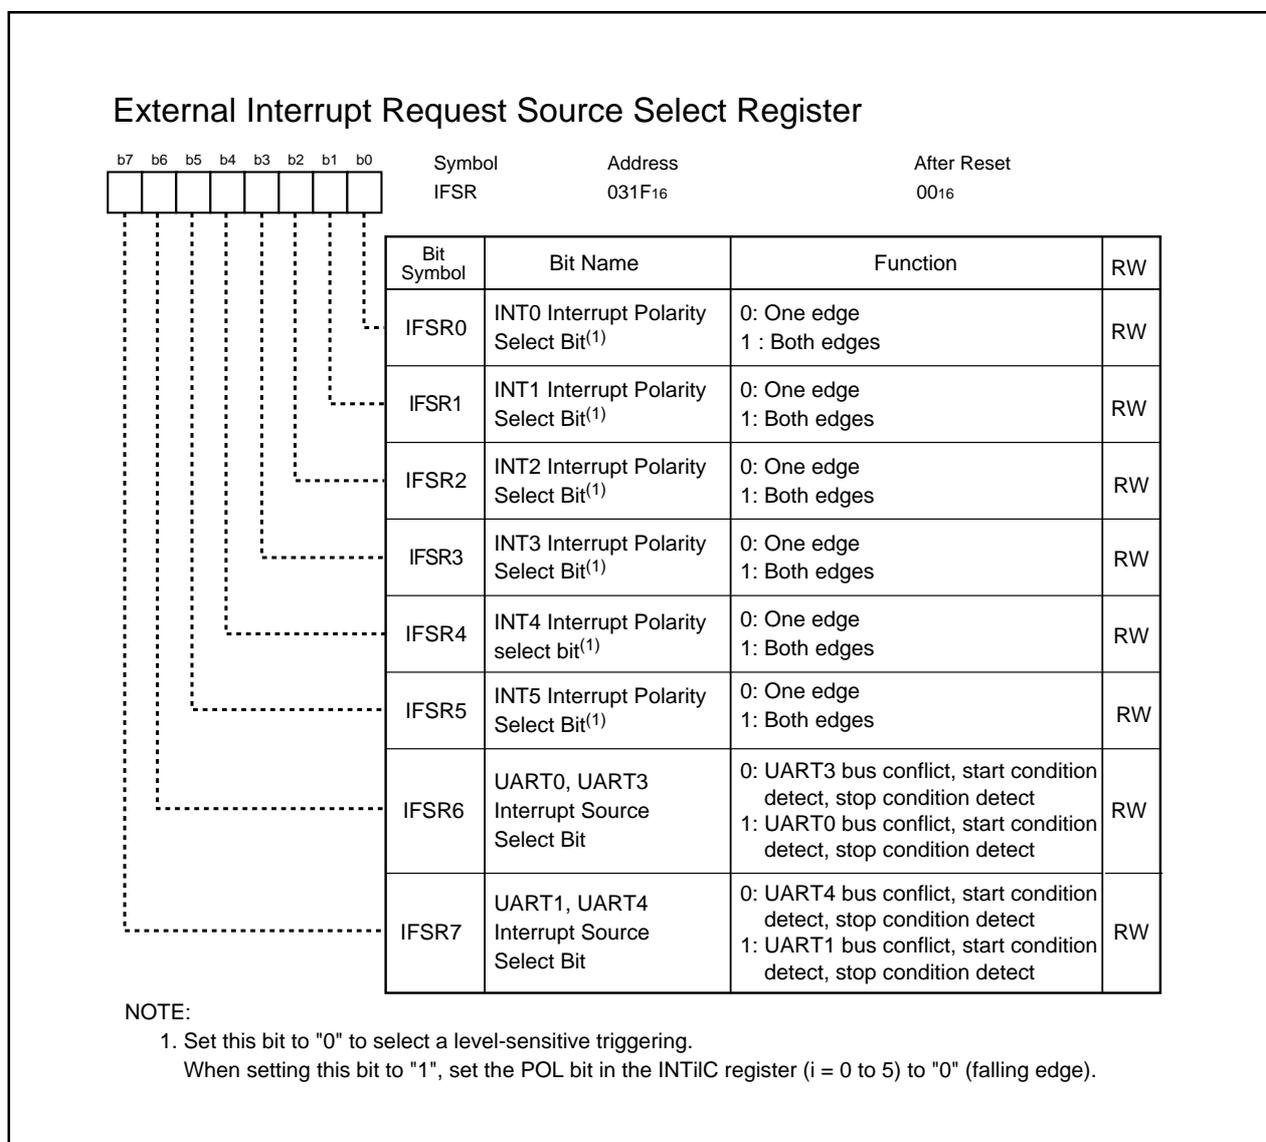

Figure 10.10 IFSR Register

10.8 $\overline{\text{NMI}}$ Interrupt

The $\overline{\text{NMI}}$ interrupt⁽¹⁾ occurs when a signal applied to the $\overline{\text{NMI}}$ pin changes from a high-level ("H") signal to a low-level ("L") signal. The $\overline{\text{NMI}}$ interrupt is a non-maskable interrupt. Although the P85/ $\overline{\text{NMI}}$ pin is used as the $\overline{\text{NMI}}$ interrupt input pin, the P8_5 bit in the P8 register indicates the input level for this pin.

NOTE:

1. When the $\overline{\text{NMI}}$ interrupt is not used, connect the $\overline{\text{NMI}}$ pin to VCC1 via a resistor. Because the $\overline{\text{NMI}}$ interrupt cannot be ignored, the pin must be connected.

10.9 Key Input Interrupt

Key input interrupt request is generated when one of the signals applied to the P104 to P107 pins in input mode is on the falling edge. The key input interrupt can be also used as key-on wake-up function to exit wait or stop mode. To use the key input interrupt, do not use P104 to P107 as A/D input ports. Figure 10.11 shows a block diagram of the key input interrupt. When an "L" signal is applied to any pins in input mode, signals applied to other pins are not detected as an interrupt request signal.

When the PSC_7 bit in the PSC register⁽²⁾ is set to "1" (key input interrupt disabled), no key input interrupt occurs regardless of interrupt control register settings. When the PSC_7 bit is set to "0", no input from a port pin is available even when in input mode.

NOTE:

2. Refer to **22. Programmable I/O Ports** about the PSC register.

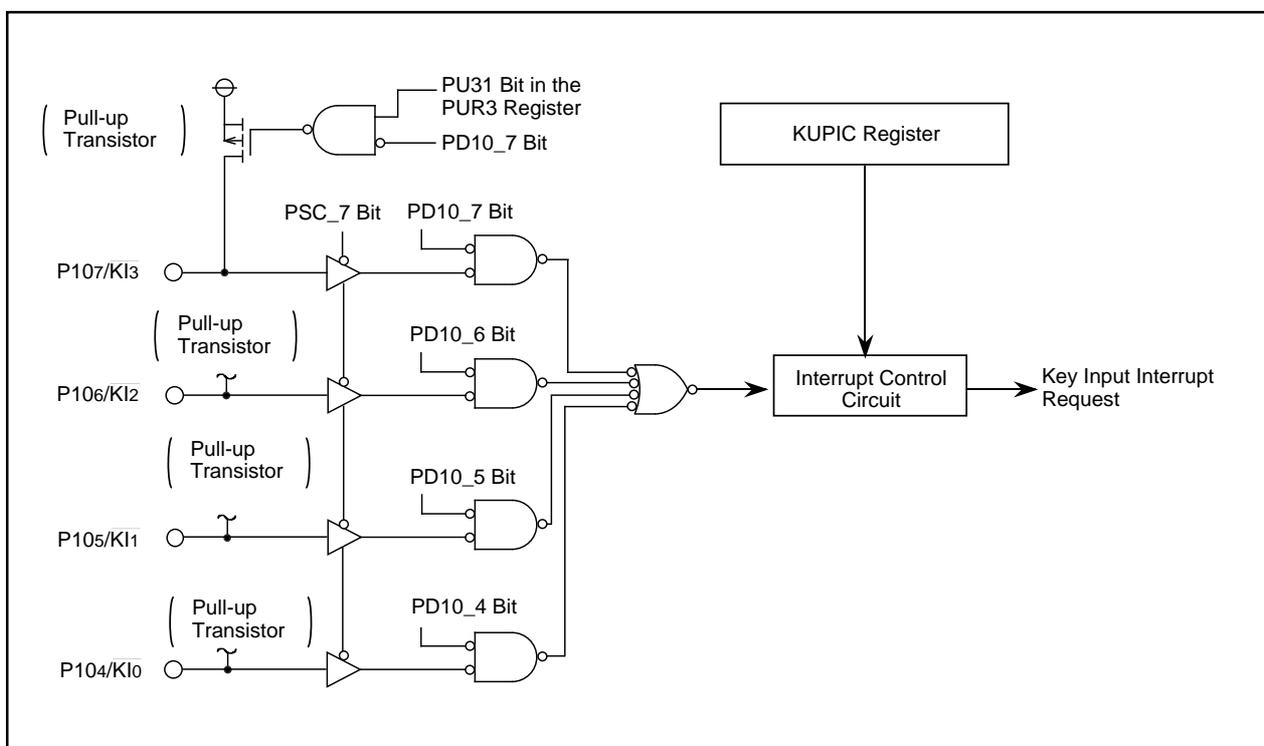

Figure 10.11 Key Input Interrupt

To use the intelligent I/O interrupt as a source to activate DMAC II, set the IRLT bit in the IIOiE register to "0" (interrupt request is used for DMAC, DMAC II) and enable an interrupt request source for the IIOiE register.

10.10 Address Match Interrupt

The address match interrupt occurs immediately before executing an instruction that is stored into an address indicated by the RMADi register (i=0 to 7). The address match interrupt can be set in eight addresses. The AIERi bit in the AIER register determines whether the interrupt is enabled or disabled. The I flag and IPL do not affect the address match interrupt.

Figure 10.12 shows registers associated with the address match interrupt.

The starting address of an instruction must be set in the RMADi register. The address match interrupt does not occur when a table data or addresses other than the starting address of the instruction is set.

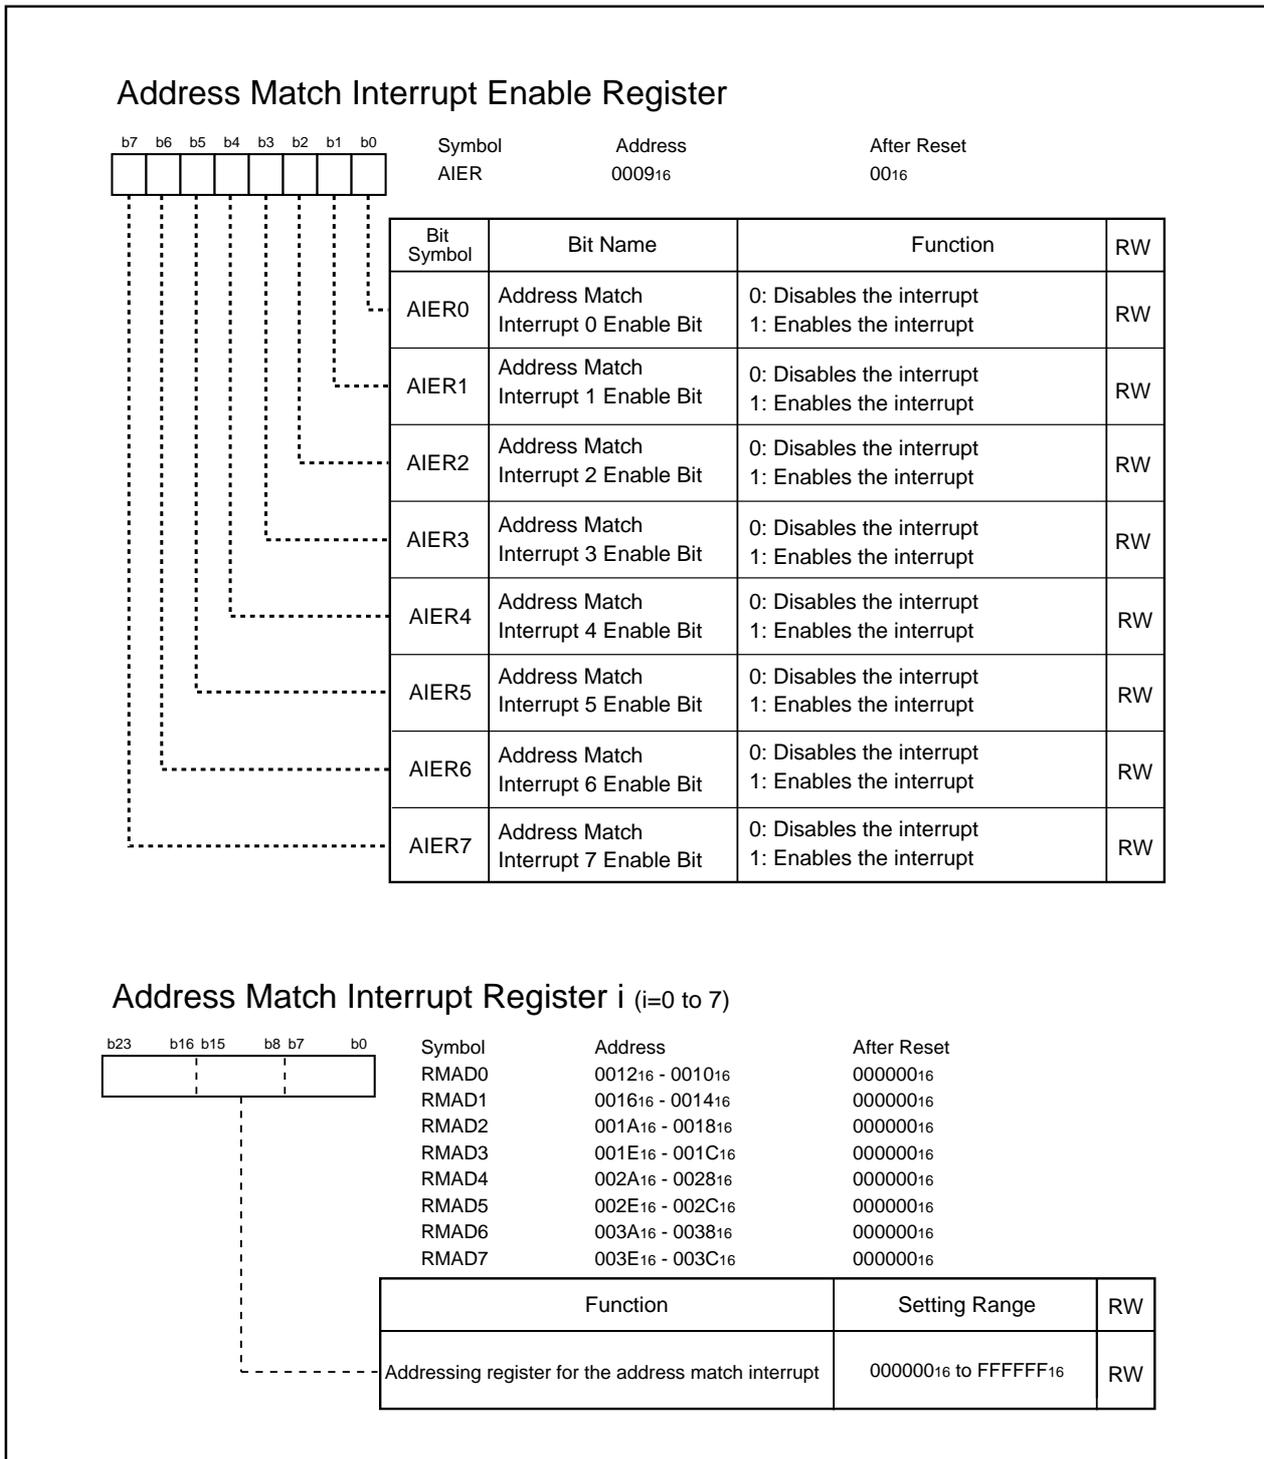

Figure 10.12 AIER Register and RMAD0 to RMAD7 Registers

10.11 Intelligent I/O Interrupt

The intelligent I/O interrupt is assigned to software interrupt numbers 44 to 48.

When using the intelligent I/O interrupt, set the IRLT bit in the IIOiE register ($i = 0$ to 4) to "1" (interrupt request for interrupt used).

Various interrupt requests cause the intelligent I/O interrupt to occur. When an interrupt request is generated with each intelligent I/O or CAN functions, the corresponding bit in the IIOiR register is set to "1" (interrupt requested). When the corresponding bit in the IIOiE register is set to "1" (interrupt enabled), the IR bit in the corresponding IIOiC register is set to "1" (interrupt requested).

After the IR bit setting changes "0" to "1", the IR bit remains set to "1" when a bit in the IIOiR register is set to "1" by another interrupt request and the corresponding bit in the IIOiE register is set to "1".

Bits in the IIOiR register are not set to "0" automatically, even if an interrupt is acknowledged. Set each bit to "0" by program. If these bit settings are left "1", all generated interrupt requests are ignored.

Figure 10.13 shows a block diagram of the intelligent I/O interrupt. Figure 10.14 shows the IIOiR register. Figure 10.15 shows the IIOiE register.

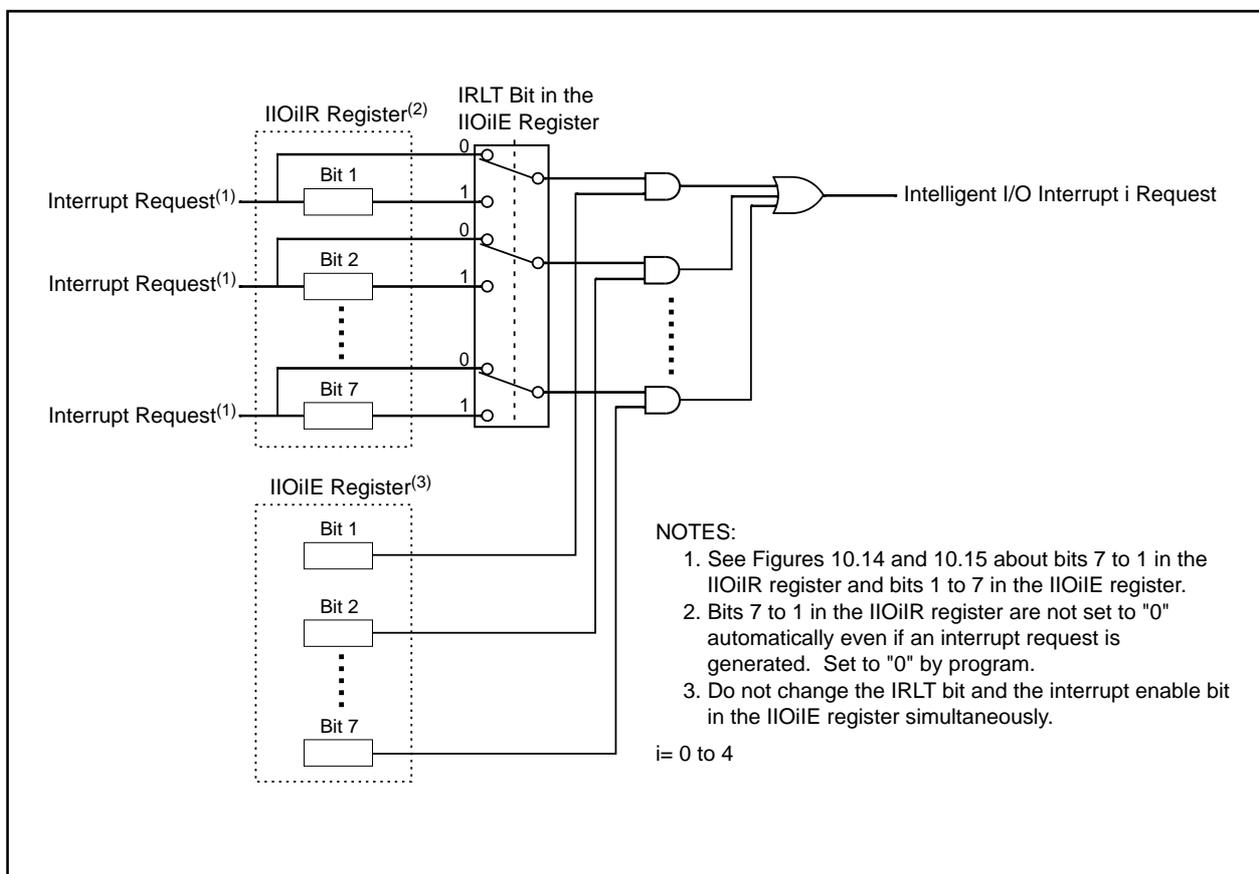

Figure 10.13 Intelligent I/O Interrupt

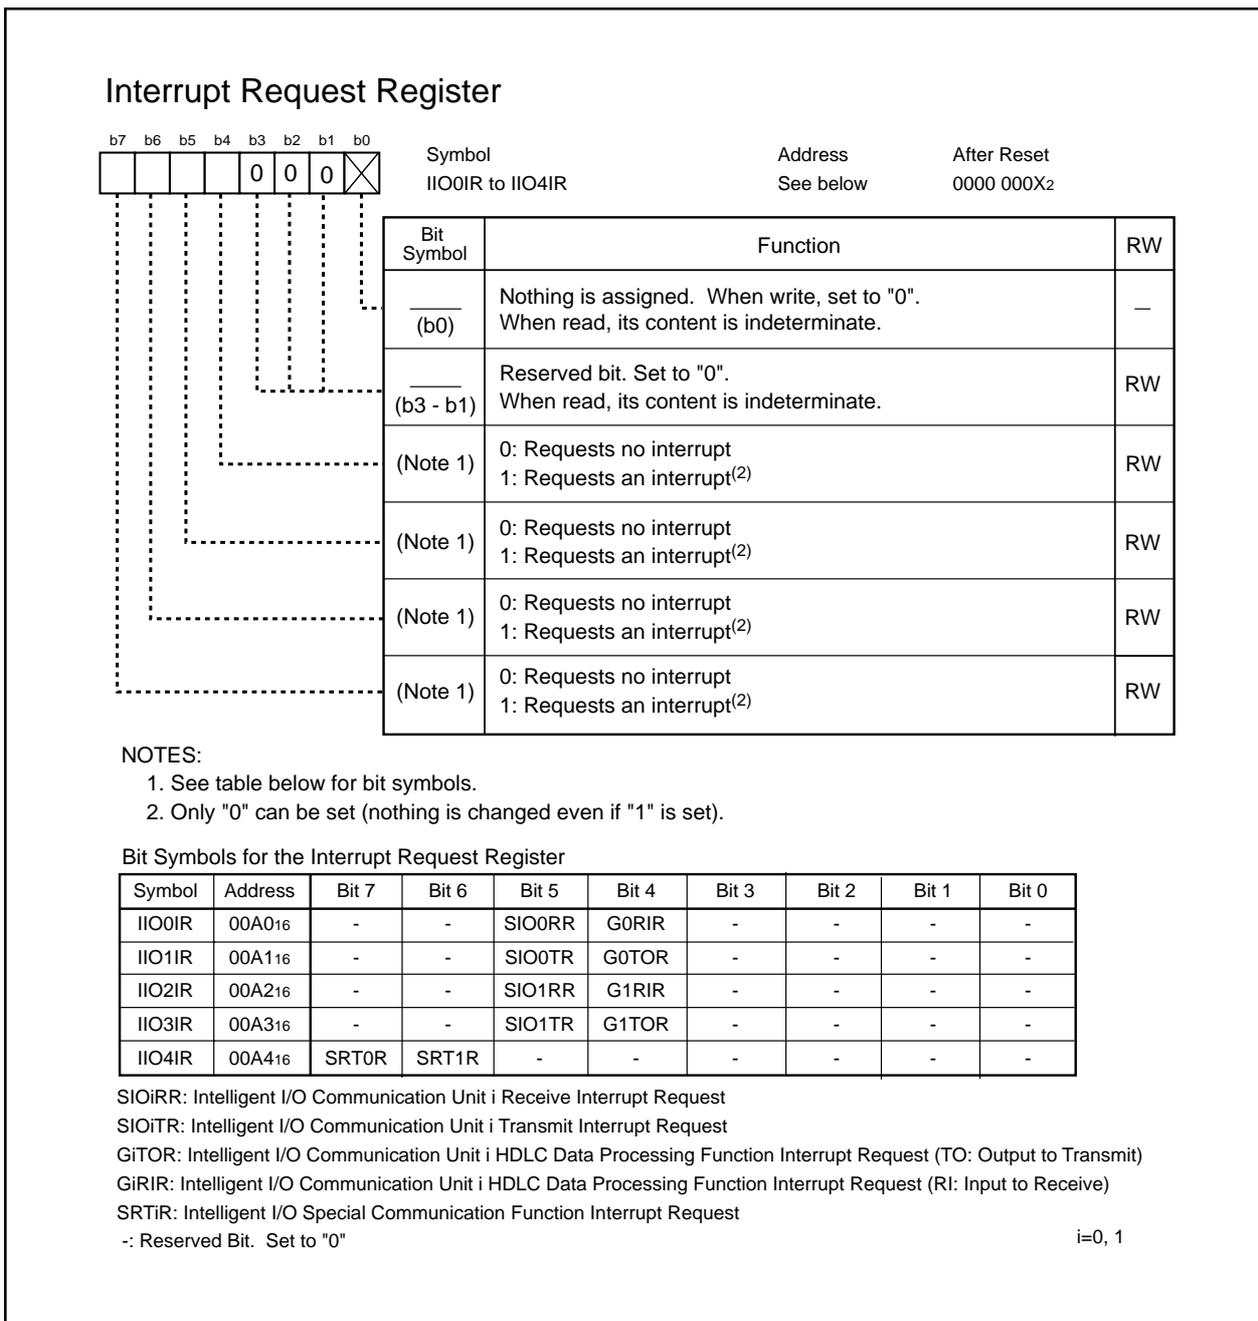

Figure 10.14 IIO0iR to IIO4iR Registers

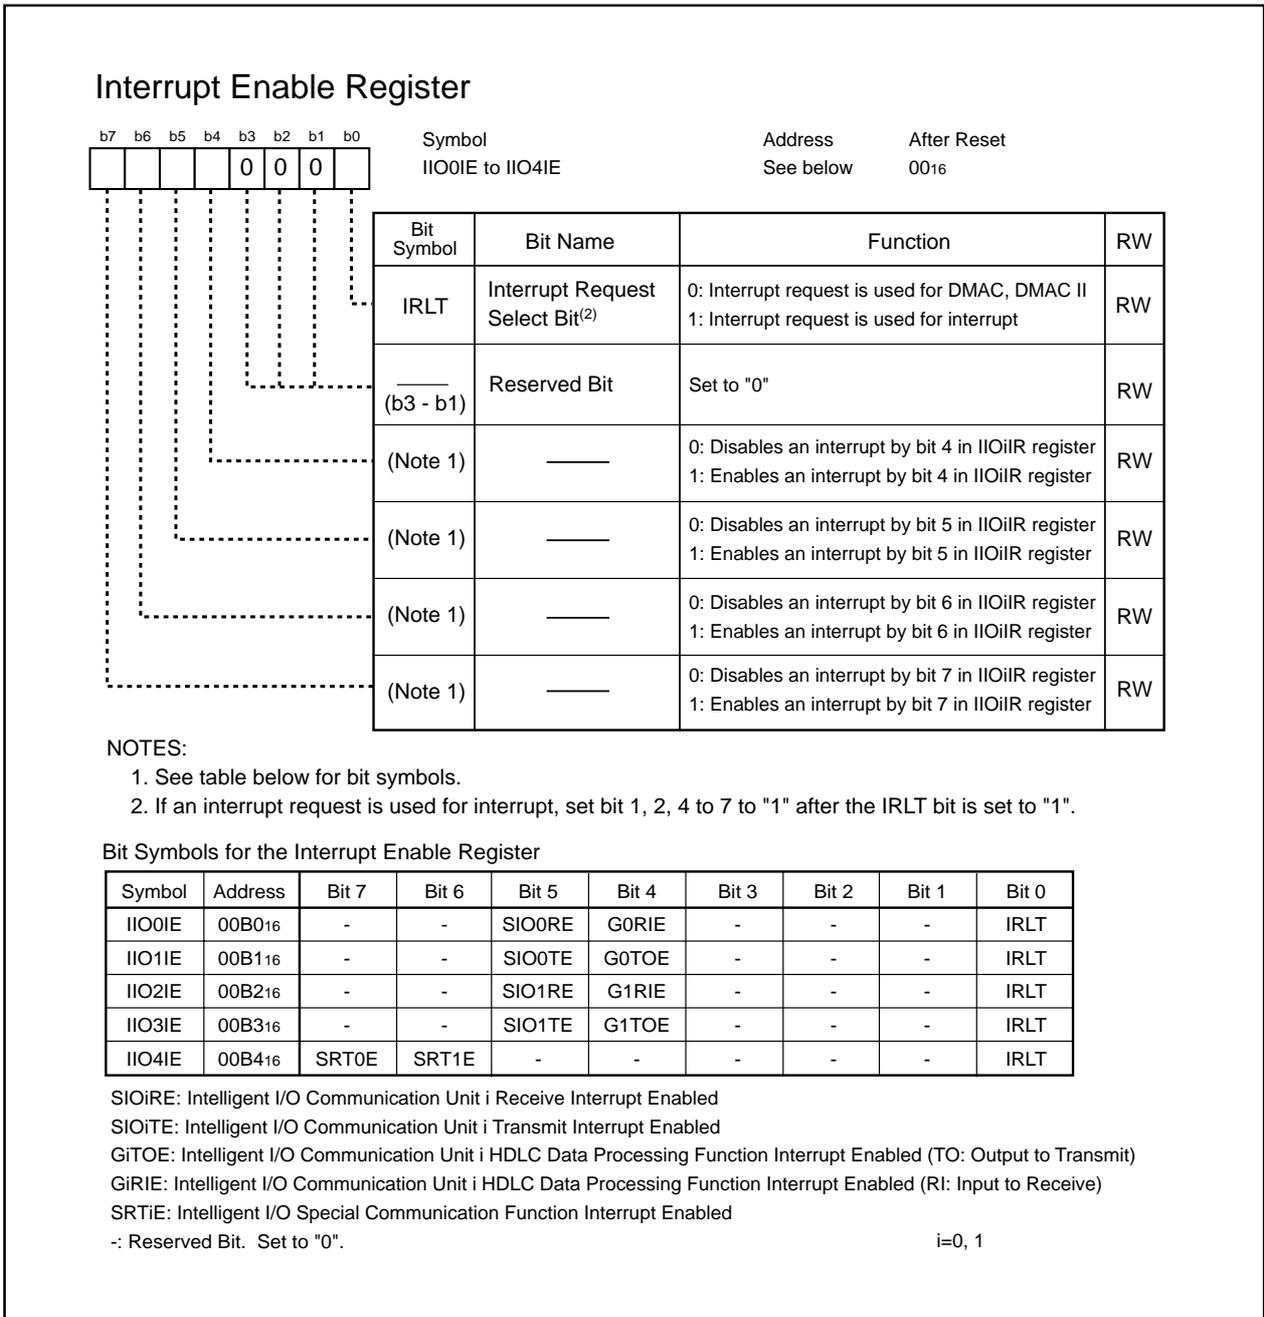

Figure 10.15 IIO0iE to IIO4iE Registers

11. Watchdog Timer

The watchdog timer monitors the program executions and detects defective program. It allows the microcomputer to trigger a reset or to generate an interrupt if the program error occurs. The watchdog timer contains a 15-bit counter, which is decremented by the CPU clock that the prescaler divides. The CM06 bit in the CM0 register determines whether a watchdog timer interrupt request or reset is generated if the watchdog timer underflows. Once the CM06 bit is set to "1", it cannot be changed to "0" (watchdog timer interrupt) by program. The CM06 bit is set to "0" only after reset.

When the main clock, on-chip oscillator clock, or PLL clock runs as the CPU clock, the WDC7 bit in the WDC register determine whether the prescaler divides the clock by 16 or by 128. When the sub clock runs as the CPU clock, the prescaler divides the clock by 2 regardless of the WDC7 bit setting. Watchdog timer cycle is calculated as follows. Marginal errors, due to the prescaler, may occur in watchdog timer cycle.

When the main clock, on-chip oscillator clock, or PLL clock is selected as the CPU clock,

$$\text{Watchdog timer cycle} = \frac{\text{Divide-by-16 or -128 prescaler} \times \text{counter value of watchdog timer (32768)}}{\text{CPU clock}}$$

When the sub clock is selected as the CPU clock,

$$\text{Watchdog timer cycle} = \frac{\text{Divide-by-2 prescaler} \times \text{counter value of watchdog timer (32768)}}{\text{CPU clock}}$$

For example, if the CPU clock frequency is 30MHz and the prescaler divides it by 16, the watchdog timer cycle is approximately 17.5 ms.

The watchdog timer is reset when the WDTS register is set and when a watchdog timer interrupt request is generated. The prescaler is reset only when the microcomputer is reset. Both watchdog timer and prescaler stop after reset. They begin counting when the WDTS register is set.

The watchdog timer and prescaler stop in stop mode, wait mode and hold state. They resume counting from the value held when the mode or state is exited.

Figure 11.1 shows a block diagram of the watchdog timer. Figure 11.2 shows registers associated with the watchdog timer.

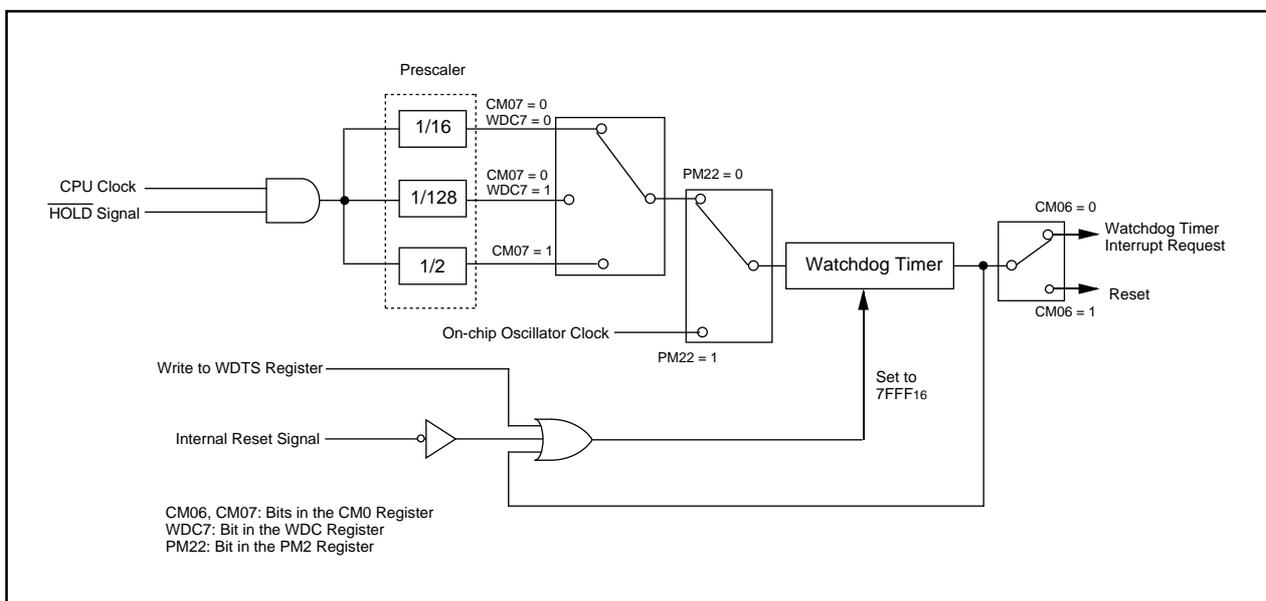

Figure 11.1 Watchdog Timer Block Diagram

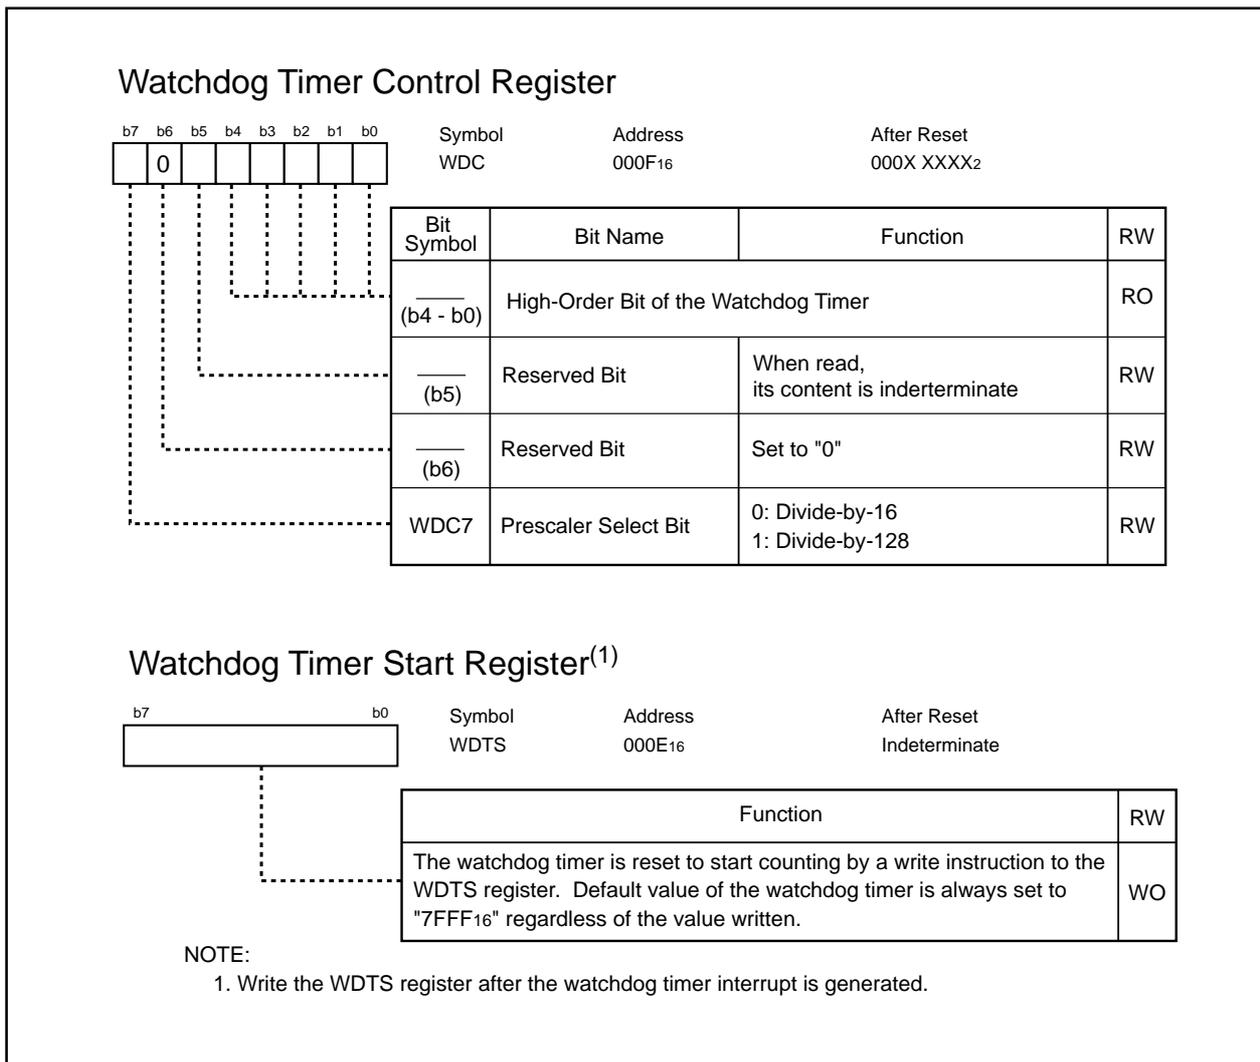

Figure 11.2 WDC Register and WDTS Register

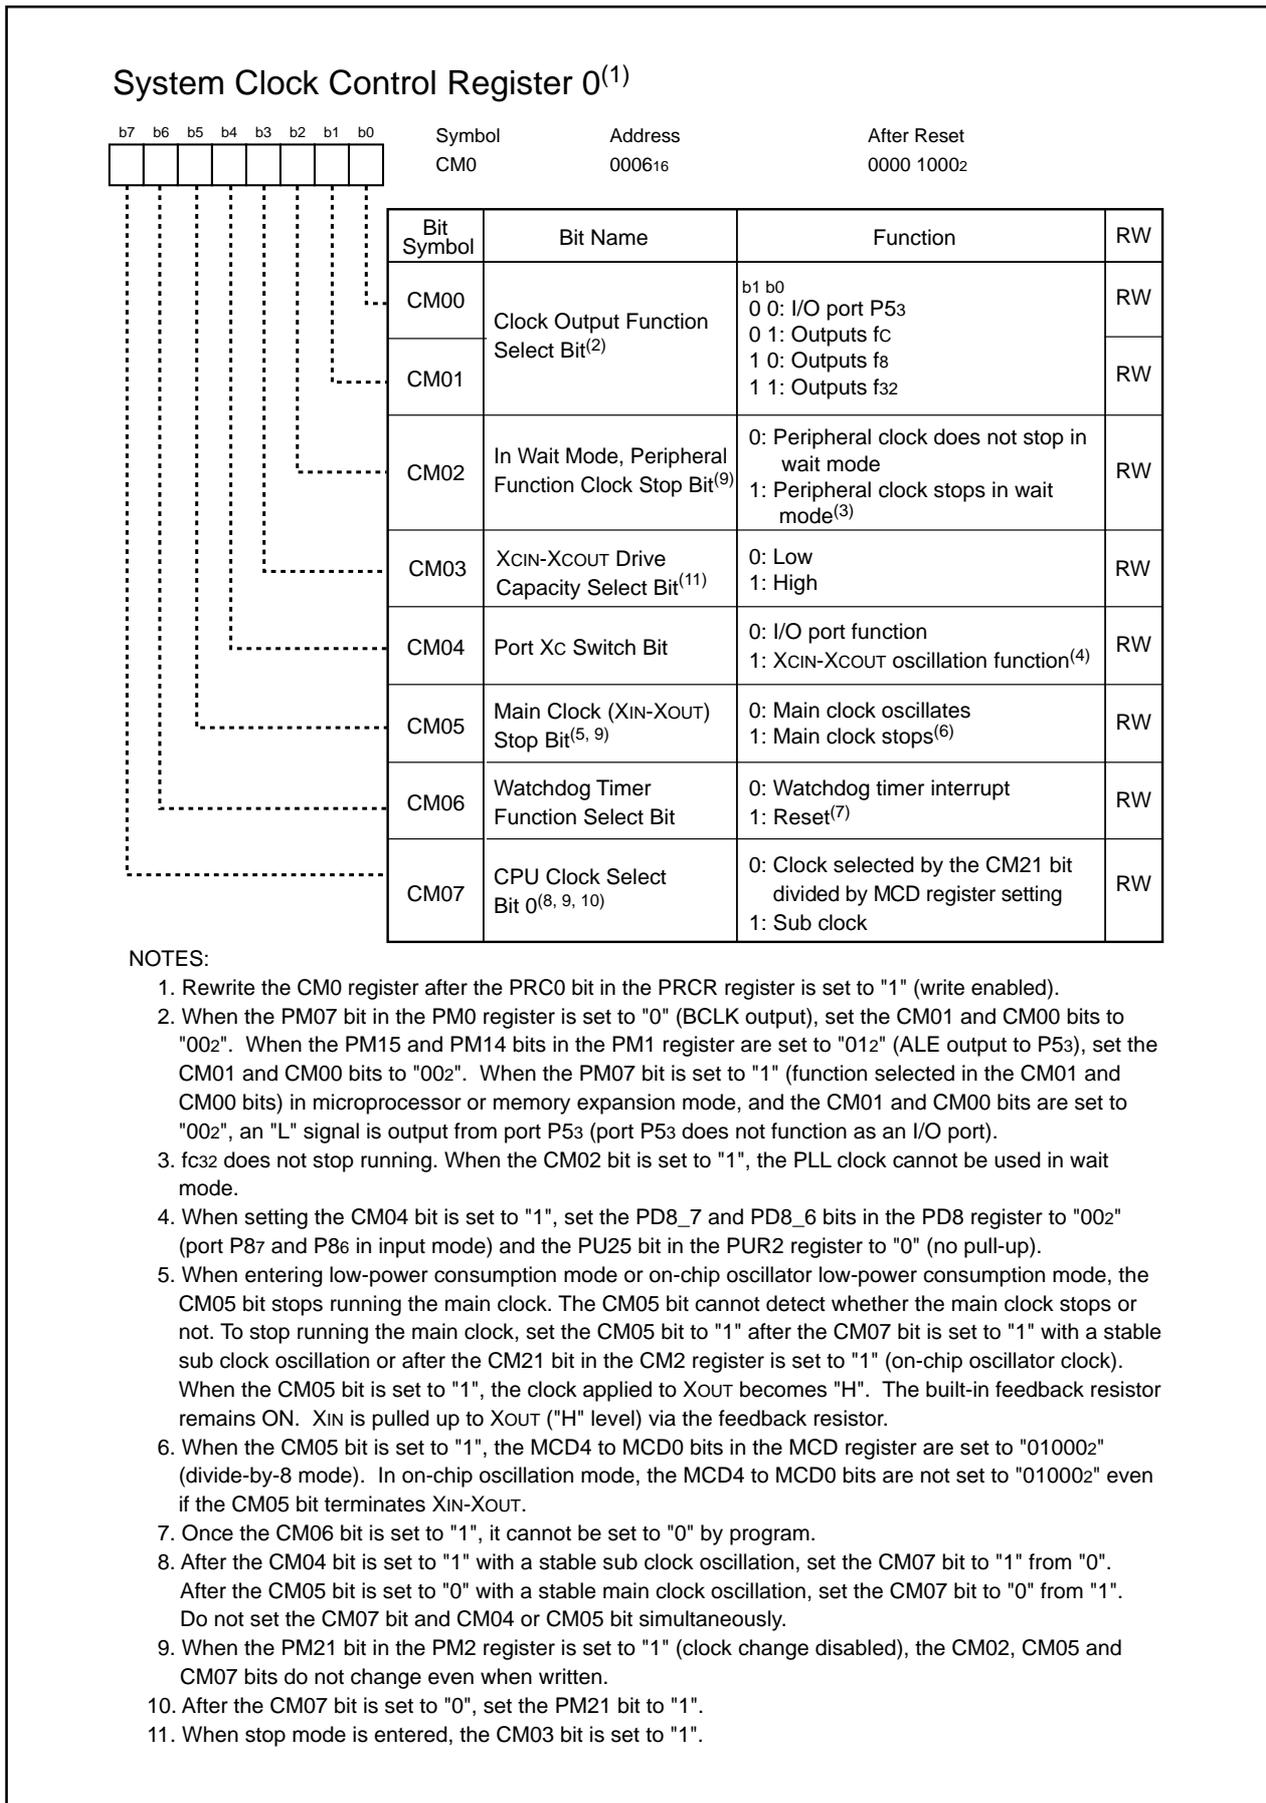

Figure 11.3 CM0 Register

11.1 Count Source Protection Mode

In count source protection mode, the on-chip oscillator clock is used as a count source for the watchdog timer. The count source protection mode allows the on-chip oscillator clock to run continuously, maintaining watchdog timer operation even if the program error occurs and the CPU clock stops running.

Follow the procedures below when using this mode.

- (1) Set the PRC0 bit in the PRCR register to "1" (write to CM0 register enabled)
- (2) Set the PRC1 bit in the PRCR register to "1" (write to PM2 register enabled)
- (3) Set the CM06 bit in the CM0 register to "1" (reset when the watchdog timer overflows)
- (4) Set the PM22 bit in the PM2 register to "1" (the on-chip oscillator clock as a count source of the watchdog timer)
- (5) Set the PRC0 bit to "0" (write to CM0 register disabled)
- (6) Set the PRC1 bit to "0" (write to PM2 register disabled)
- (7) Write to the WDTS register (the watchdog timer starts counting)

The followings will occur when the PM22 bit is set to "1".

- The on-chip oscillator starts oscillating and the on-chip oscillator clock becomes a count source for the watchdog timer.

$$\text{Watchdog timer cycle} = \frac{\text{Counter value of watchdog timer (32768)}}{\text{On-chip oscillator clock}}$$

- Write to the CM10 bit in the CM1 register is disabled. (The bit setting remains unchanged even if set it to "1". The microcomputer does not enter stop mode.)
- In wait mode or hold state, the watchdog timer continues running. However, the watchdog timer interrupt cannot be used to exit wait mode.

12. DMAC

This microcomputer contains four DMAC (direct memory access controller) channels that allow data to be sent to memory without using the CPU. DMAC transmits a 8- or 16-bit data from a source address to a destination address whenever a transmit request occurs. DMA0 and DMA1 must be prioritized if using DMAC. DMA2 and DMA3 share registers required for high-speed interrupts. High-speed interrupts cannot be used when using three or more DMAC channels.

The CPU and DMAC use the same data bus, but DMAC has a higher bus access privilege than the CPU. The cycle-steal method employed on DMAC enables high-speed operation between a transfer request and the complete transmission of 16-bit (word) or 8-bit (byte) data. Figure 12.1 shows a mapping of registers to be used for DMAC. Table 12.1 lists specifications of DMAC. Figures 12.2 to 12.5 show registers associated with DMAC.

Because the registers shown in Figure 12.1 are allocated in the CPU, use the LDC instruction to write to the registers. To set the DCT2, DCT3, DRC2, DRC3, DMA2 and DMA3 registers, set the B flag to "1" (register bank 1) and set the R0 to R3, A0, A1 registers with the MOV instruction.

To set the DSA2 and DSA3 registers, set the B flag to "1" and set the SB and FB registers with the LDC instruction. To set the DRA2 and DRA3 registers, set the SVP and VCT registers with the LDC instruction.

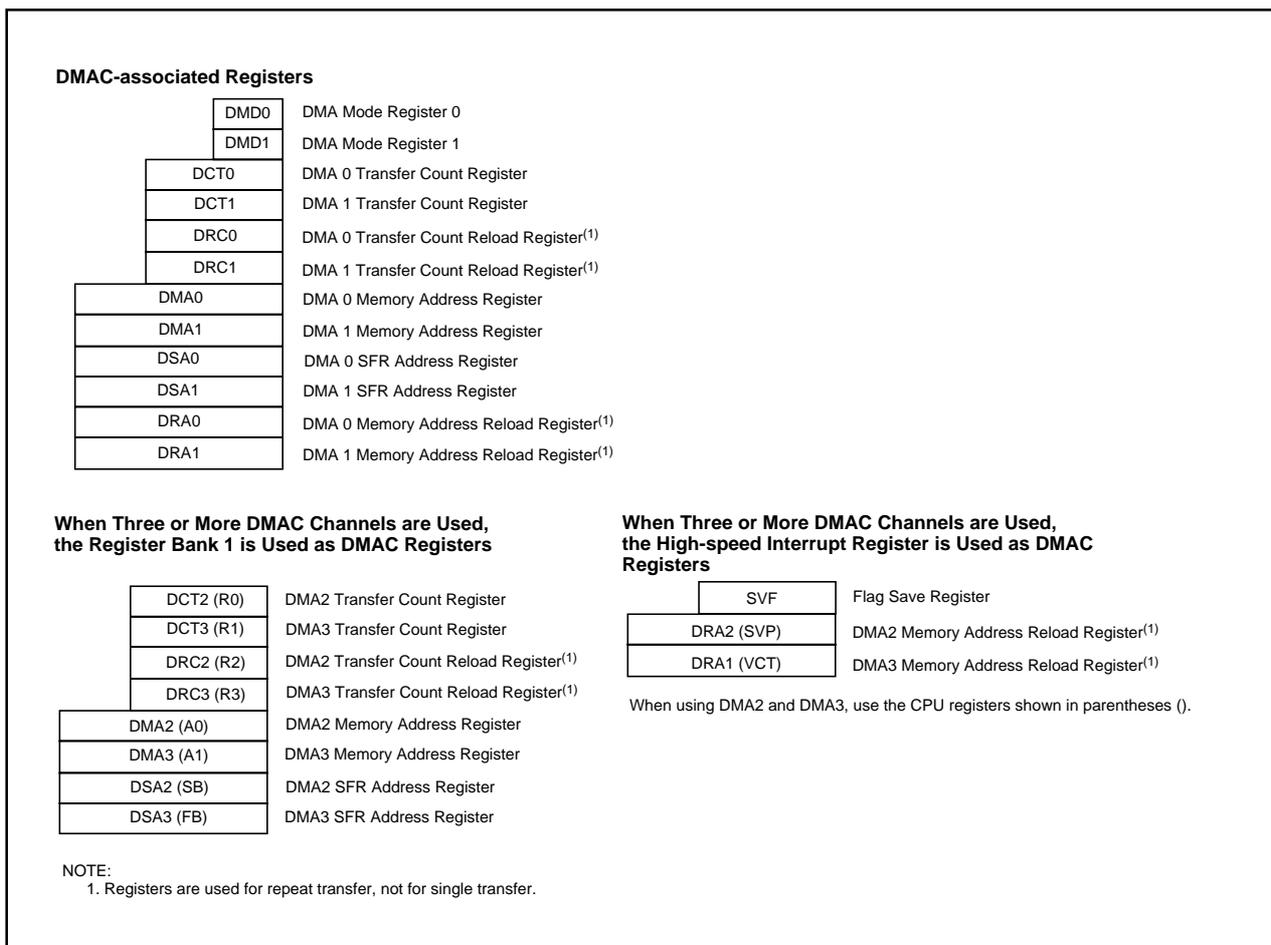

Figure 12.1 Register Mapping for DMAC

DMAC starts a data transfer by setting the DSR bit in the DMiSL register (i=0 to 3) or by using an interrupt request, generated by the functions determined by the DSEL 4 to DSEL0 bits in the DMiSL register, as a DMA request. Unlike interrupt requests, the I flag and interrupt control register do not affect DMA. Therefore, a DMA request can be acknowledged even if an interrupt is disabled and cannot be acknowledged. In addition, the IR bit in the interrupt control register does not change when a DMA request is acknowledged.

Table 12.1 DMAC Specifications

Item	Specification	
Channels	4 channels (cycle-steal method)	
Transfer Memory Space	<ul style="list-style-type: none"> From a desired address in a 16-Mbyte space to a fixed address in a 16-Mbyte space From a fixed address in a 16-Mbyte space to a desired address in a 16-Mbyte space 	
Maximum Bytes Transferred	128 Kbytes (when a 16-bit data is transferred) or 64 Kbytes (with an 8-bit data is transferred)	
DMA Request Source ⁽¹⁾	Falling edge or both edges of signals applied to the INT0 to INT3 pins Timers A0 to A4 interrupt requests Timers B0 to B5 interrupt requests UART0 to UART4 transmit and receive interrupt requests A/D0 conversion interrupt request Intelligent I/O interrupt request Software trigger	
Channel Priority	DMA0 > DMA1 > DMA2 > DMA3 (DMA0 has highest priority)	
Transfer Unit	8 bits, 16 bits	
Destination Address	Forward/fixed (forward and fixed directions cannot be specified when specifying source and destination addresses simultaneously)	
Transfer Mode	Single Transfer	Transfer is completed when the DCTi register (i = 0 to 3) is set to "0000 ₁₆ "
	Repeat Transfer	When the DCTi register is set to "0000 ₁₆ ", the value of the DRCi register is reloaded into the DCTi register and the DMA transfer is continued
DMA Interrupt Request Generation Timing	When the DCTi register changes "0001 ₁₆ " to "0000 ₁₆ "	
DMA Startup	Single Transfer	DMA starts when a DMA request is generated after the DCTi register is set to "0001 ₁₆ " or more and the MDi1 and MDi0 bits in the DMDj register (j = 0,1) are set to "012" (single transfer)
	Repeat Transfer	DMA starts when a DMA request is generated after the DCTi register is set to "0001 ₁₆ " or more and the MDi1 and MDi0 bits are set to "112" (repeat transfer)
DMA Stop	Single Transfer	DMA stops when the MDi1 and MDi0 bits are set to "002" (DMA disabled) and the DCTi register is set to "0000 ₁₆ " (0 DMA transfer) by DMA transfer or write
	Repeat Transfer	DMA stops when the MDi1 and MDi0 bits are set to "002" and the DCTi register is set to "0000 ₁₆ " and the DRCi register set to "0000 ₁₆ "
Reload Timing to the DCTi or DMAi Register	When the DCTi register is set to "0000 ₁₆ " from "0001 ₁₆ " in repeat transfer mode	
DMA Transfer Cycles	Minimum 3 cycles between SFRs and internal RAM	

NOTE:

1. The IR bit in the interrupt control register does not change when a DMA request is acknowledged.

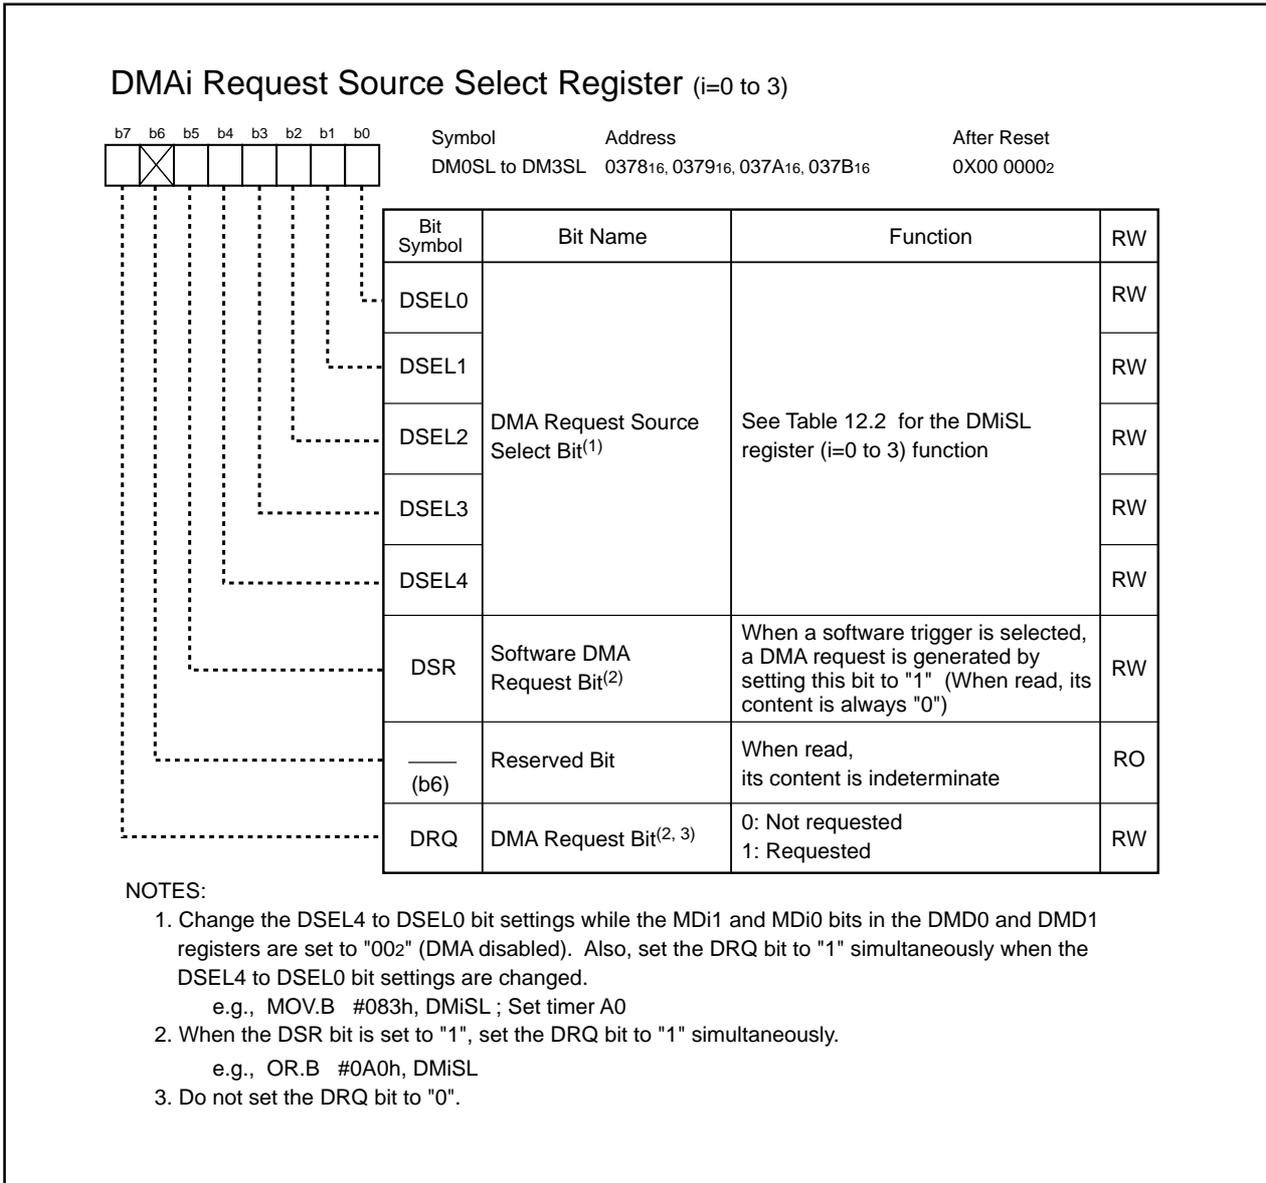

Figure 12.2 DM0SL to DM3SL Registers

Table 12.2 DMiSL Register (i=0 to 3) Function

Setting Value b4 b3 b2 b1 b0	DMA Request Source

1 1 1 1 1	_____	Intelligent I/O Interrupt 1 Request	_____	Intelligent I/O Interrupt 3 Request

NOTES:

1. If the $\overline{INT3}$ pin is used for data bus in memory expansion mode or microprocessor mode, a DMA3 interrupt request cannot be generated by a signal applied to the $\overline{INT3}$ pin.
2. The falling edge and both edges of signals applied to the \overline{INTj} pin (j=0 to 3) cause a DMA request generation. The \overline{INT} interrupt (the POL bit in the INTjIC register, the LVS bit, the IFSR register) is not affected and vice versa.
3. Use the UkSMR register and UkSMR2 register (k=0 to 4) to switch between the UARTk receive and ACK interrupt as a DMA request source.
To use the ACK interrupt for a DMA request, set the IICM bit in the UkSMR register to "1" and the IICM2 bit in the UkSMR2 register to "0".

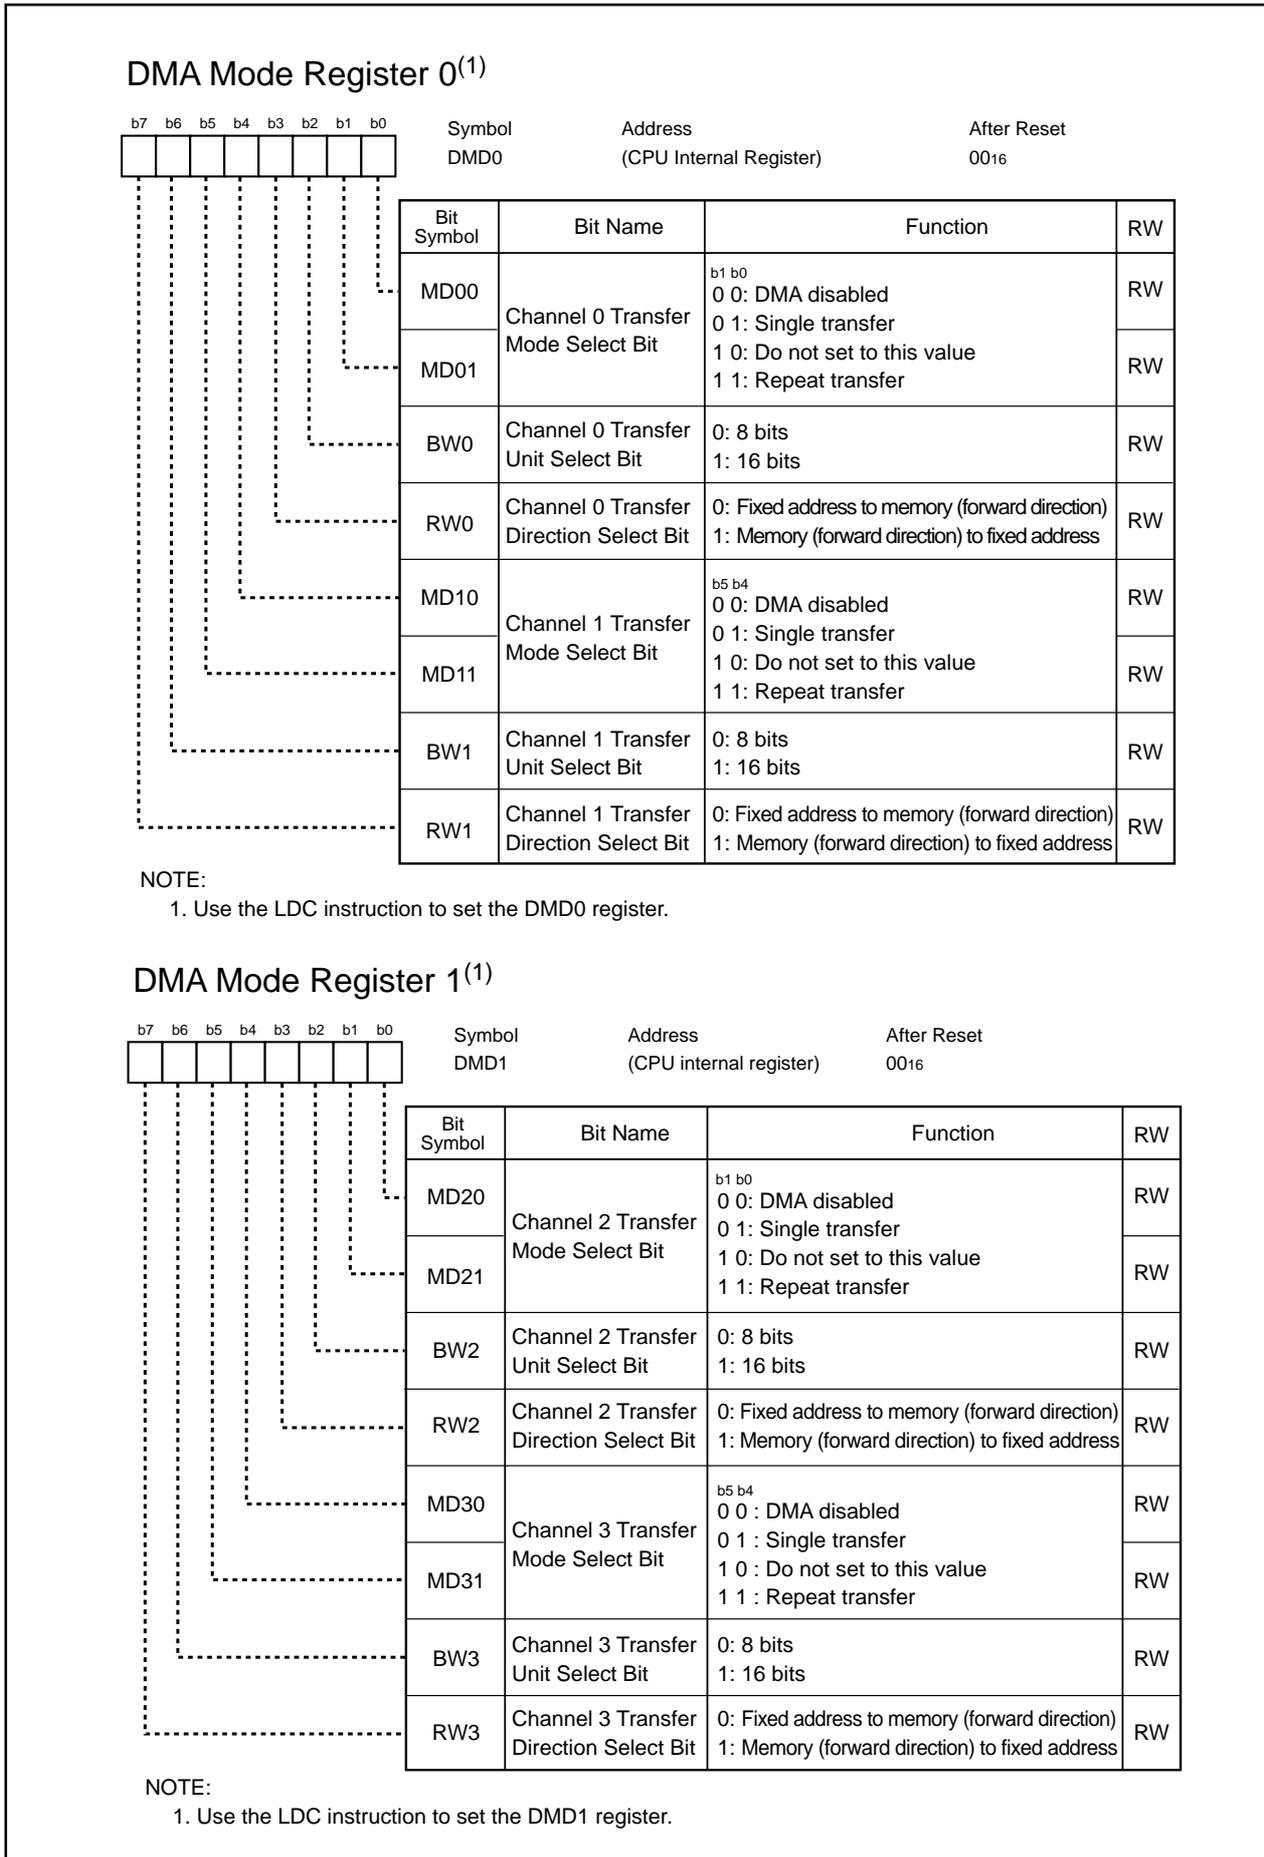

Figure 12.3 DMD0 and DMD1 Registers

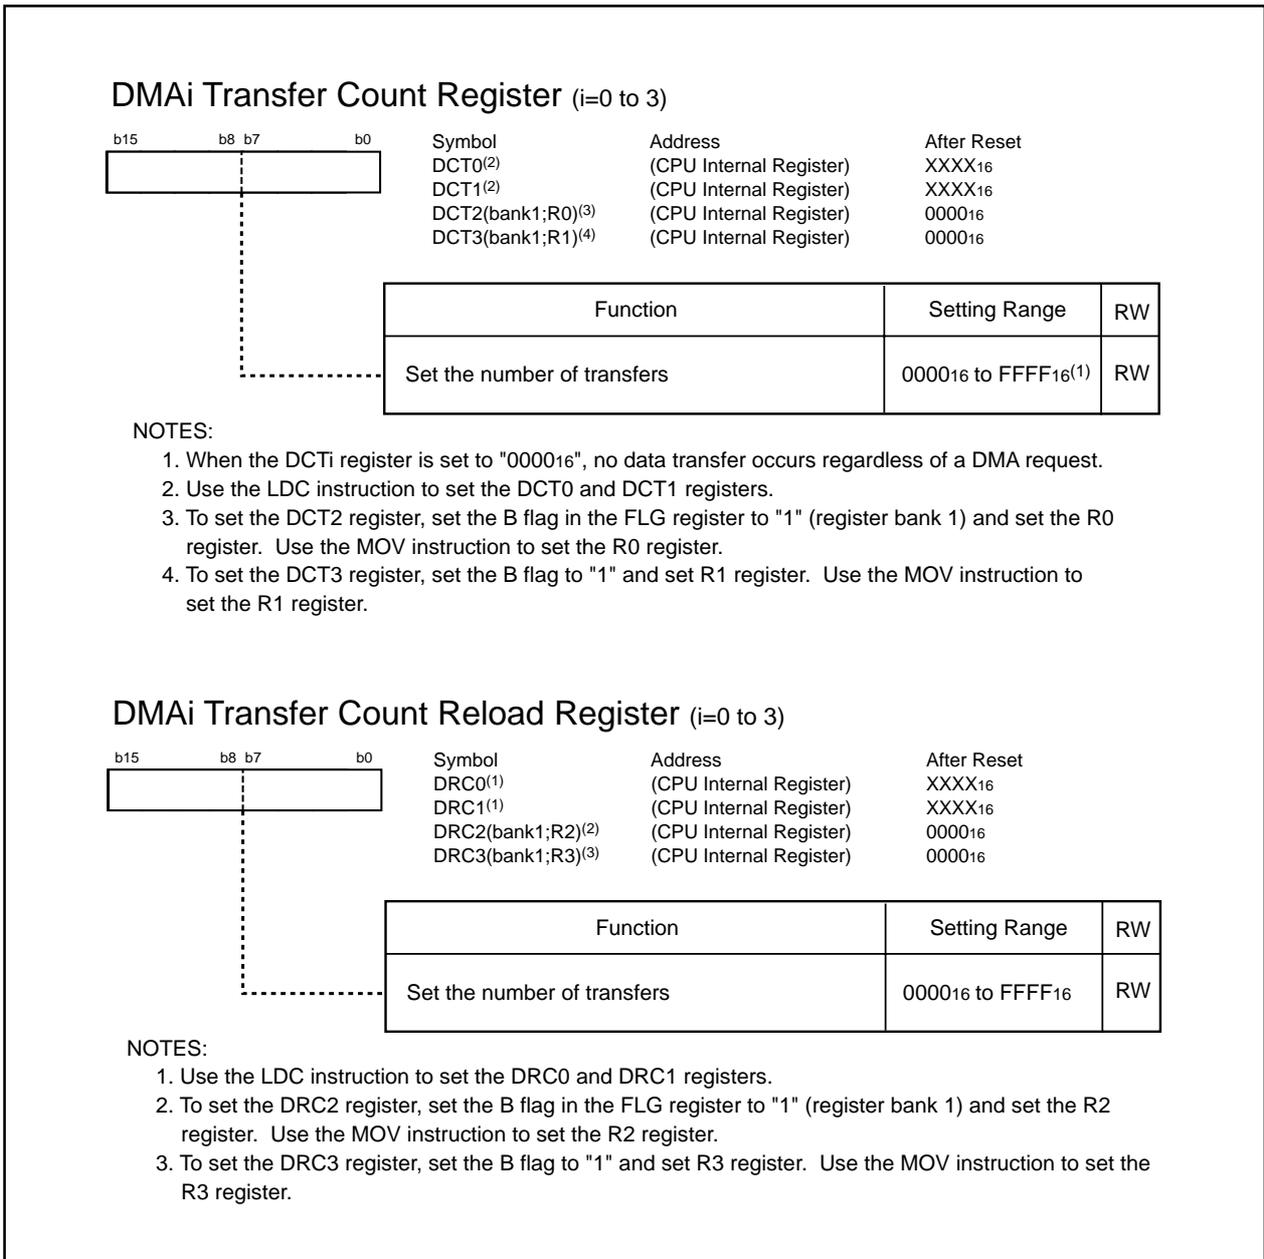

Figure 12.4 DCT0 to DCT3 Registers and DRC0 to DRC3 Registers

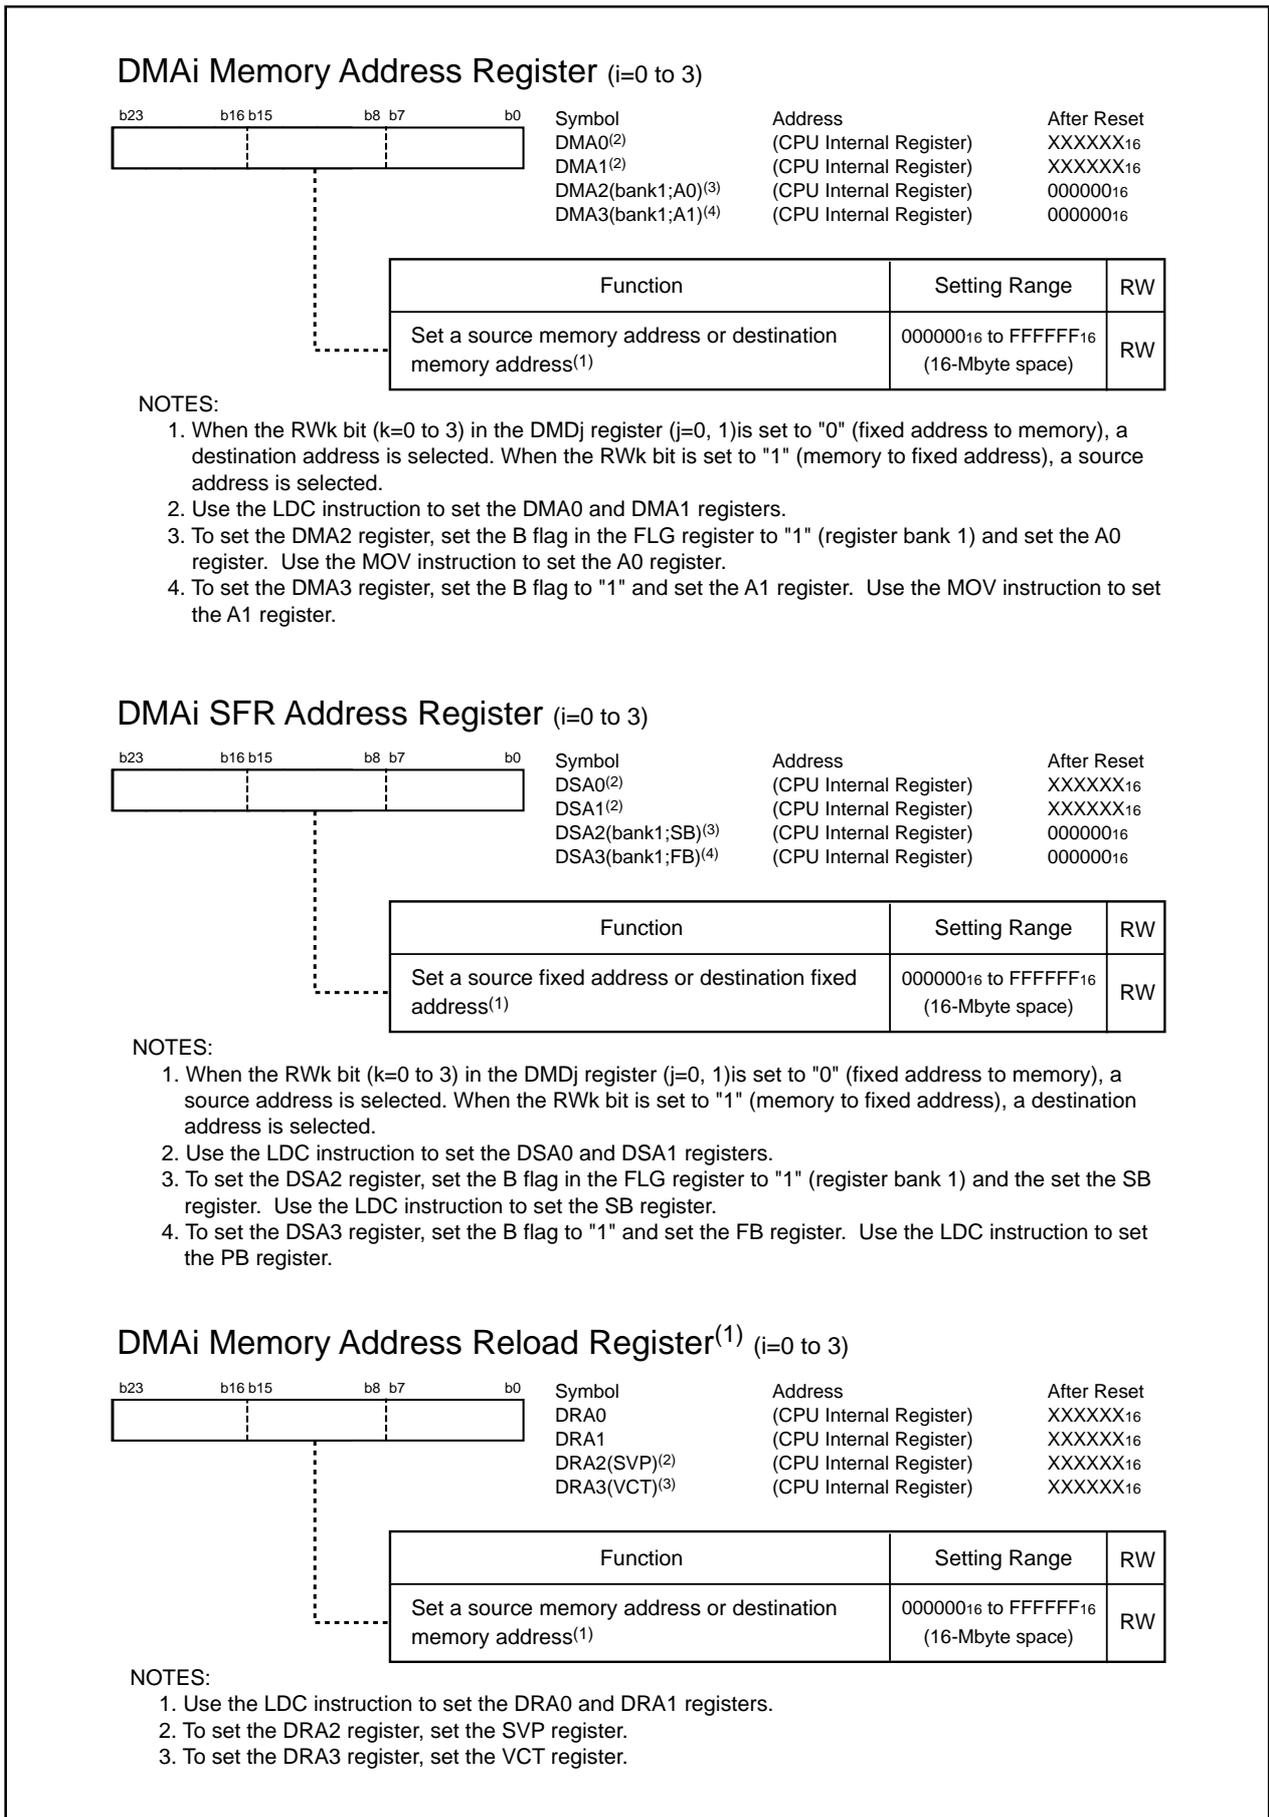

Figure 12.5 DMA0 to DMA3 Registers, DSA0 to DSA3 Registers and DRA0 to DRA3 Registers

12.1 Transfer Cycle

Transfer cycle contains a bus cycle to read data from a memory or the SFR area (source read) and a bus cycle to write data to a memory space or the SFR area (destination write). The number of read and write bus cycles depends on source and destination addresses. In memory expansion mode and microprocessor mode, the number of read and write bus cycles also depends on DS register setting. Software wait state insertion and the $\overline{\text{RDY}}$ signal make a bus cycle longer.

12.1.1 Effect of Source and Destination Addresses

When a 16-bit data is transferred with a 16-bit data bus and a source address starting with an odd address, source read cycle is incremented by one bus cycle, compared to a source address starting with an even address.

When a 16-bit data is transferred with a 16-bit data bus and a destination address starting with an odd address, a destination write cycle is incremented by one bus cycle, compared to a destination address starting with an even address.

12.1.2 Effect of the DS Register

In an external space in memory expansion or microprocessor mode, transfer cycle varies depending on the data bus used at the source and destination addresses. See **Figure 8.1** for details about the DS register.

- When an 8-bit data bus (the DS_i bit in the DS register is set to "0" (i=0 to 3)), accessing both source address and destination address, is used to transfer a 16-bit data, 8-bit data is transferred twice. Therefore, two bus cycles are required to read the data and another two bus cycles to write the data.
- When an 8-bit data bus (the DS_i bit in the DS register is set to "0" (i=0 to 3)), accessing source address, and a 16-bit data bus, accessing destination address, are used to transfer a 16-bit data, 8-bit data is read twice but is written once as 16-bit data. Therefore, two bus cycles are required for reading and one bus cycle is for writing.
- When a 16-bit data bus, accessing source address, and an 8-bit data bus, accessing destination address, are used to transfer a 16-bit data, 16-bit data is read once and 8-bit data is written twice. Therefore, one bus cycle is required for reading and two bus cycles is for writing.

12.1.3 Effect of Software Wait State

When the SFR area or memory space with software wait states is accessed, the number of CPU clock cycles is incremented by software wait states.

Figure 12.6 shows an example of a transfer cycle for the source-read bus cycle. In Figure 12.6, the number of source-read bus cycles is illustrated under different conditions, provided that the destination address is an address of an external space with the destination-write cycle as two CPU clock cycles (=one bus cycle). In effect, the destination-write bus cycle is also affected by each condition and the transfer cycles change accordingly. To calculate a transfer cycle, apply respective conditions to both destination-write bus cycle and source-read bus cycle. As shown in example (2) of Figure 12.6, when an 8-bit data bus, accessing both source and destination addresses, is used to transfer a 16-bit data, two bus cycles each are required for the source-read bus cycle and destination-write bus cycle.

12.1.4 Effect of $\overline{\text{RDY}}$ Signal

In memory expansion or microprocessor mode, the $\overline{\text{RDY}}$ signal affects a bus cycle if a source address or destination address is allocated address in an external space. Refer to **7.2.6 RDY Signal** for details.

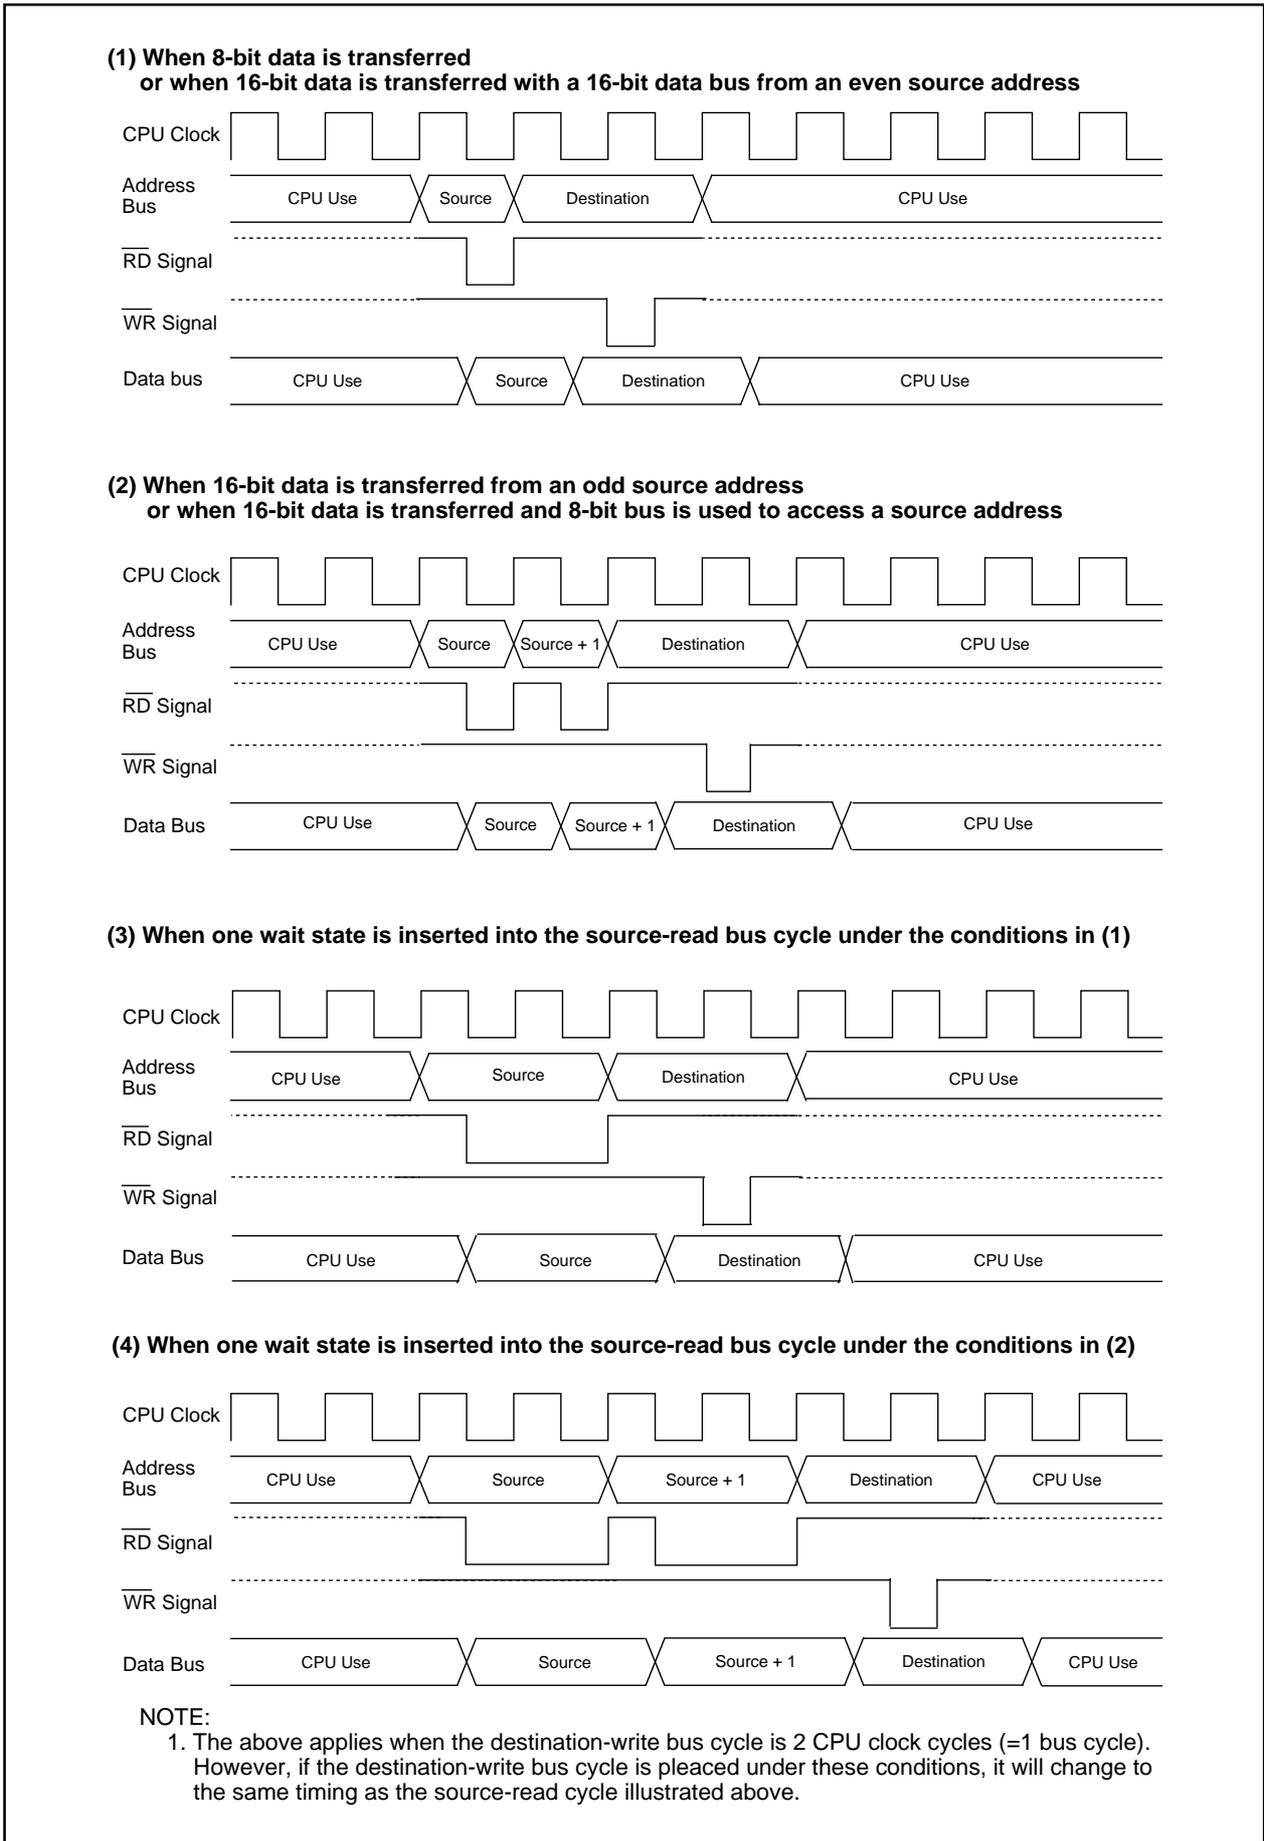

Figure 12.6 Transfer Cycle Examples with the Source-Read Bus Cycle

12.2 DMAC Transfer Cycle

The number of DMAC transfer cycle can be calculated as follows.

Any combination of even or odd transfer read and write addresses are possible. Table 12.3 lists the number of DMAC transfer cycles. Table 12.4 lists coefficient j, k.

$$\text{Transfer cycles per transfer} = \text{Number of read cycle} \times j + \text{Number of write cycle} \times k$$

Table 12.3 DMAC Transfer Cycles

Transfer Unit	Bus Width	Access Address	Single-Chip Mode		Memory Expansion Mode Microprocessor Mode	
			Read Cycle	Write Cycle	Read Cycle	Write Cycle
8-bit transfers (BWi bit in the DMDp register = 0)	16-bit	Even	1	1	1	1
		Odd	1	1	1	1
	8-bit	Even	—	—	1	1
		Odd	—	—	1	1
16-bit transfers (BWi bit = 1)	16-bit	Even	1	1	1	1
		Odd	2	2	2	2
	8-bit	Even	—	—	2	2
		Odd	—	—	2	2

i = 0 to 3, p = 0, 1

Table 12.4 Coefficient j, k

Internal Space			External Space
Internal RAM with no wait state	Internal RAM with a wait state	SFR area	j and k BCLK cycles shown in Table 7.5.
j=1 k=1	j=2 k=2	j=2 k=2	Add one cycle to j or k cycles when inserting a recovery cycle.

j, k = 2 to 9

12.3 Channel Priority and DMA Transfer Timing

When multiple DMA requests are generated in the same sampling period, between the falling edge of the CPU clock and the next falling edge, the DRQ bit in the DMiSL register (i=0 to 3) is set to "1" (requested) simultaneously. Channel priority in this case is: DMA0 > DMA1 > DMA2 > DMA3.

Figure 12.7 shows an example of the DMA transfer by external source.

In Figure 12.7, the DMA0 request having highest priority is received first to start a transfer when a DMA0 request and DMA1 request are generated simultaneously. After one DMA0 transfer is completed, the bus privilege is returned to the CPU. When the CPU has completed one bus access, the DMA1 transfer starts. After one DMA1 transfer is completed, the privilege is again returned to the CPU.

In addition, DMA requests cannot be counted up since each channel has one DRQ bit. Therefore, when DMA requests, as DMA1 in Figure 12.7, occur more than once before receiving bus privilege, the DRQ bit is set to "0" as soon as privilege is acquired. The bus privilege is returned to the CPU when one transfer is completed.

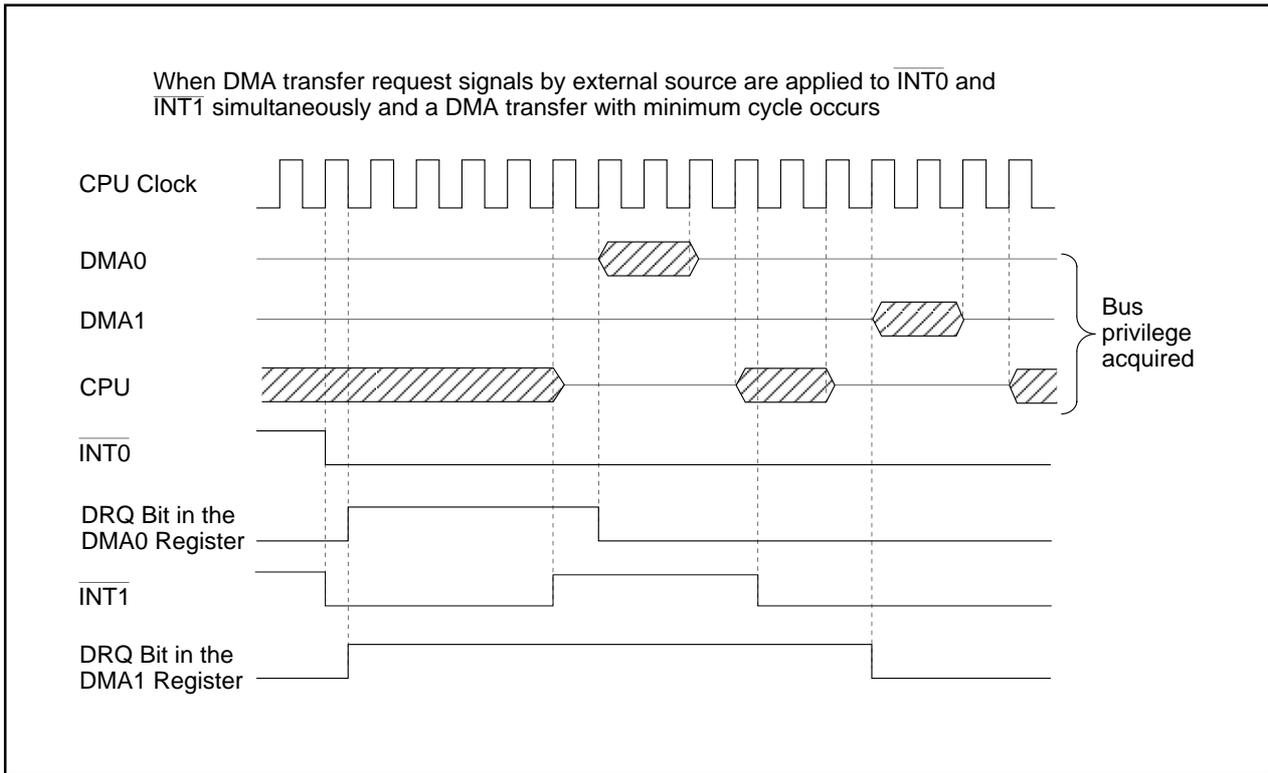

Figure 12.7 DMA Transfer by External Source

13. DMAC II

DMAC II performs memory-to-memory transfer, immediate data transfer and calculation transfer, which transfers the sum of two data added by an interrupt request from any peripheral functions.

Table 13.1 lists specifications of DMAC II.

Table 13.1 DMAC II Specifications

Item	Specification
DMAC II Request Source	Interrupt requests generated by all peripheral functions when the ILVL2 to ILVL0 bits are set to "1112"
Transfer Data	<ul style="list-style-type: none"> • Data in memory is transferred to memory (memory-to-memory transfer) • Immediate data is transferred to memory (immediate data transfer) • Data in memory (or immediate data) + data in memory are transferred to memory (calculation transfer)
Transfer Block	8 bits or 16 bits
Transfer Space	64-Kbyte space in addresses 00000 ₁₆ to 0FFFF ₁₆ ^(1, 2)
Transfer Direction	Fixed or forward address Selected separately for each source address and destination address
Transfer Mode	Single transfer, burst transfer
Chained Transfer Function	Parameters (transfer count, transfer address and other information) are switched when transfer counter reaches zero
End-of-Transfer Interrupt	Interrupt occurs when a transfer counter reaches zero
Multiple Transfer Function	Multiple data can be transferred by a generated request for one DMAC II transfer

NOTES:

1. When transferring a 16-bit data to destination address 0FFFF₁₆, it is transferred to 0FFFF₁₆ and 10000₁₆. The same transfer occurs when the source address is 0FFFF₁₆.
2. The actual space where transfer can occur is limited due to internal RAM capacity.

13.1 DMAC II Settings

DMAC II can be made available by setting up the following registers and tables.

- RLVL register
- DMAC II Index
- Interrupt control register of the peripheral function causing a DMAC II request
- The relocatable vector table of the peripheral function causing a DMAC II request
- IRLT bit in the IIOiE register (i=0 to 4) to use the intelligent I/O

Refer to **10. Interrupts** for details on the IIOiE register.

13.1.1 RLVL Register

When the DMAII bit is set to "1" (DMAC II transfer) and the FSIT bit to "0" (normal interrupt), DMAC II is activated by an interrupt request from any peripheral function with the ILVL2 to ILVL0 bits in the interrupt control register set to "1112" (level 7).

Figure 13.1 shows the RLVL register.

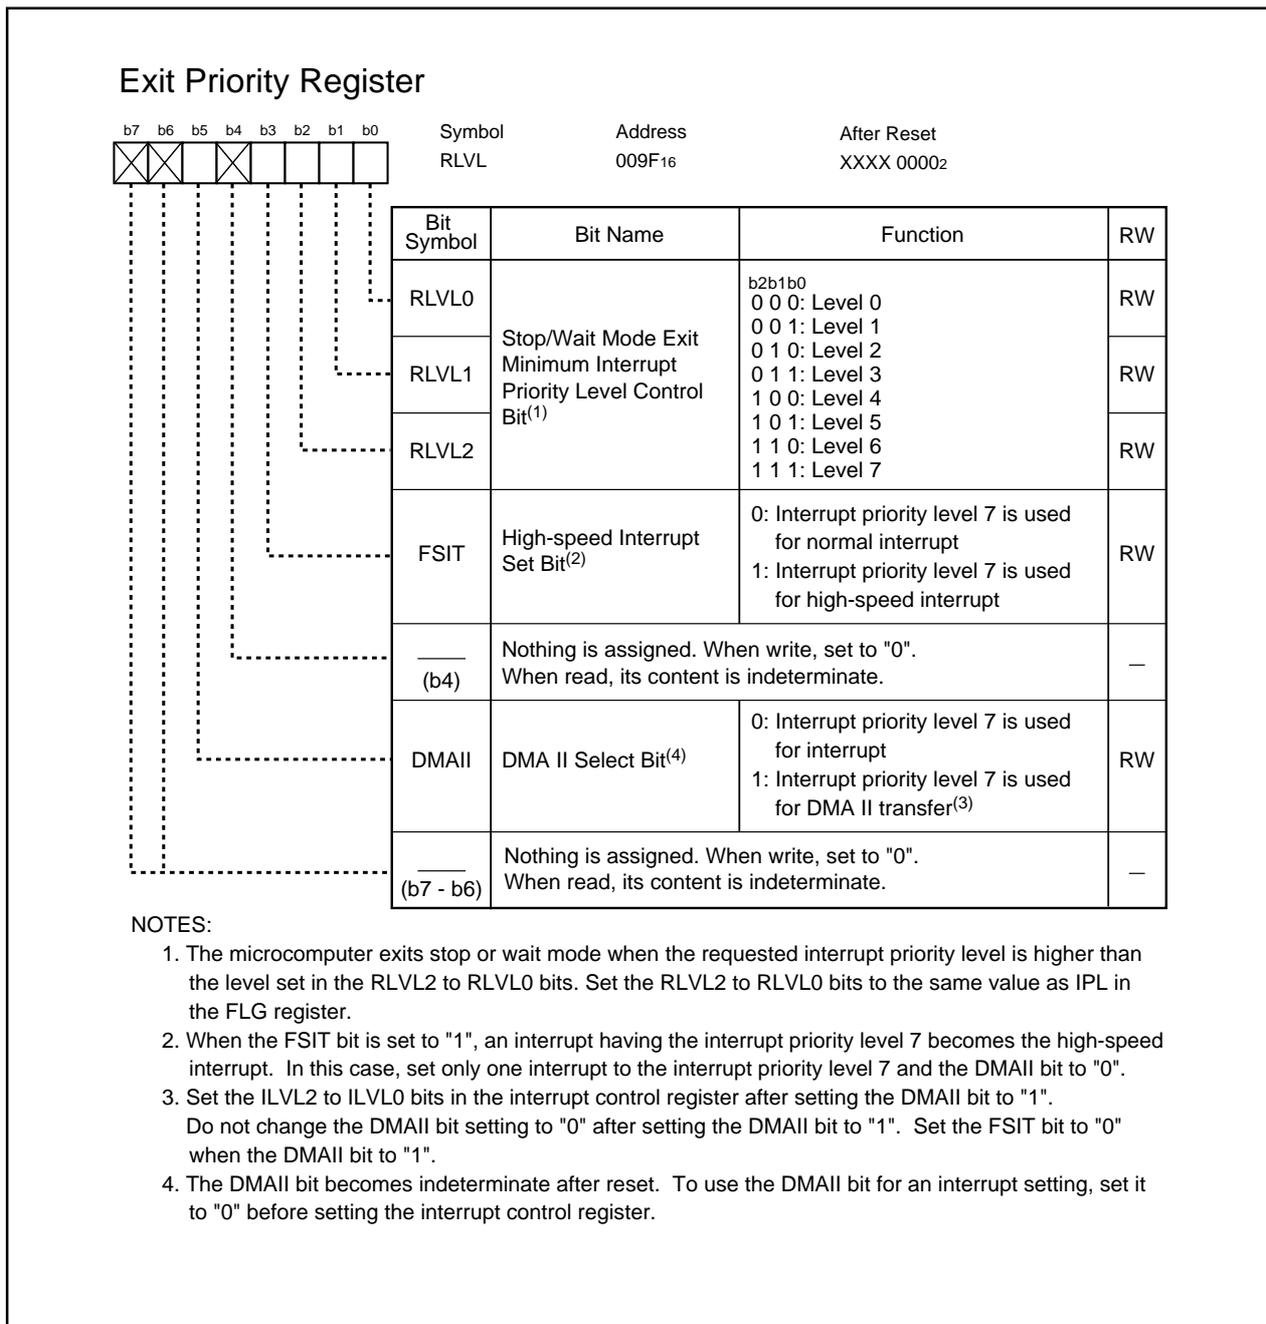

Figure 13.1 RLVL Register

13.1.2 DMAC II Index

The DMAC II index is a data table which comprises 8 to 18 bytes (maximum 32 bytes when the multiple transfer function is selected). The DMAC II index stores parameters for transfer mode, transfer counter, source address (or immediate data), operation address as an address to be calculated, destination address, chained transfer address, and end-of-transfer interrupt address.

This DMAC II index must be located on the RAM area.

Figure 13.2 shows a configuration of the DMAC II index. Table 13.2 lists a configuration of the DMAC II index in transfer mode.

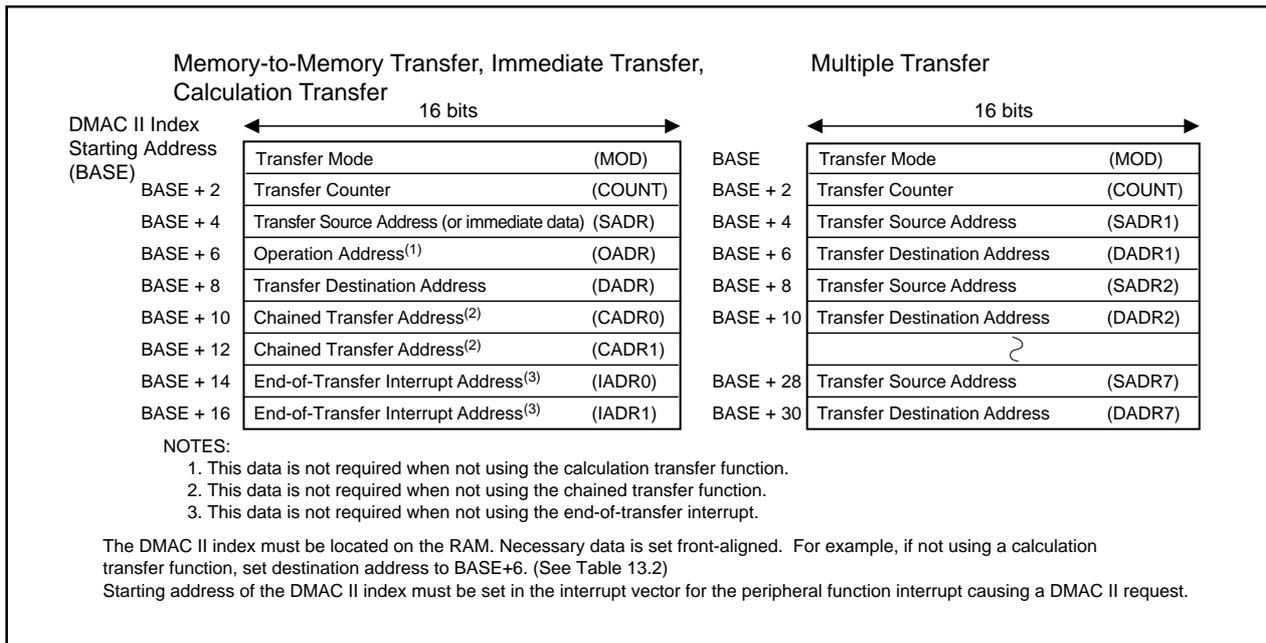

Figure 13.2 DMAC II Index

The followings are details of the DMAC II index. Set these parameters in the specified order listed in Table 13.2, according to DMAC II transfer mode.

- **Transfer mode (MOD)**

Two-byte data is required to set transfer mode. Figure 13.3 shows a configuration for transfer mode.

- **Transfer counter (COUNT)**

Two-byte data is required to set the number of transfer.

- **Transfer source address (SADR)**

Two-byte data is required to set the source memory address or immediate data.

- **Operation address (OADR)**

Two-byte data is required to set a memory address to be calculated. Set this data only when using the calculation transfer function.

- **Transfer destination address (DADR)**

Two-byte data is required to set the destination memory address.

- **Chained transfer address (CADR)**

Four-byte data is required to set the starting address of the DMAC II index for the next transfer. Set this data only when using the chained transfer function.

- **End-of-transfer interrupt address (IADR)**

Four-byte data is required to set a jump address for end-of-transfer interrupt processing. Set this data only when using the end-of-transfer interrupt.

Table 13.2 DMAC II Index Configuration in Transfer Mode

Transfer Data	Memory-to-Memory Transfer /Immediate Data Transfer				Calculation Transfer				Multiple Transfer		
	Not Used	Used	Not Used	Used	Not Used	Used	Not Used	Used			
Chained Transfer	Not Used	Used	Not Used	Used	Not Used	Used	Not Used	Used	Not Available		
End-of-Transfer Interrupt	Not Used	Not Used	Used	Used	Not Used	Not Used	Used	Used	Not Available

	COUNT	COUNT	COUNT	COUNT	COUNT	COUNT	COUNT	COUNT	COUNT		
	SADR	SADR	SADR	SADR	SADR	SADR	SADR	SADR	SADR1		
	DADR	DADR	DADR	DADR	OADR	OADR	OADR	OADR	DADR1		
	8 bytes	CADR0	12 bytes	IADR0	12 bytes	10 bytes	DADR	14 bytes	DADR	14 bytes	18 bytes
		CADR1		IADR1			CADR0		IADR0		

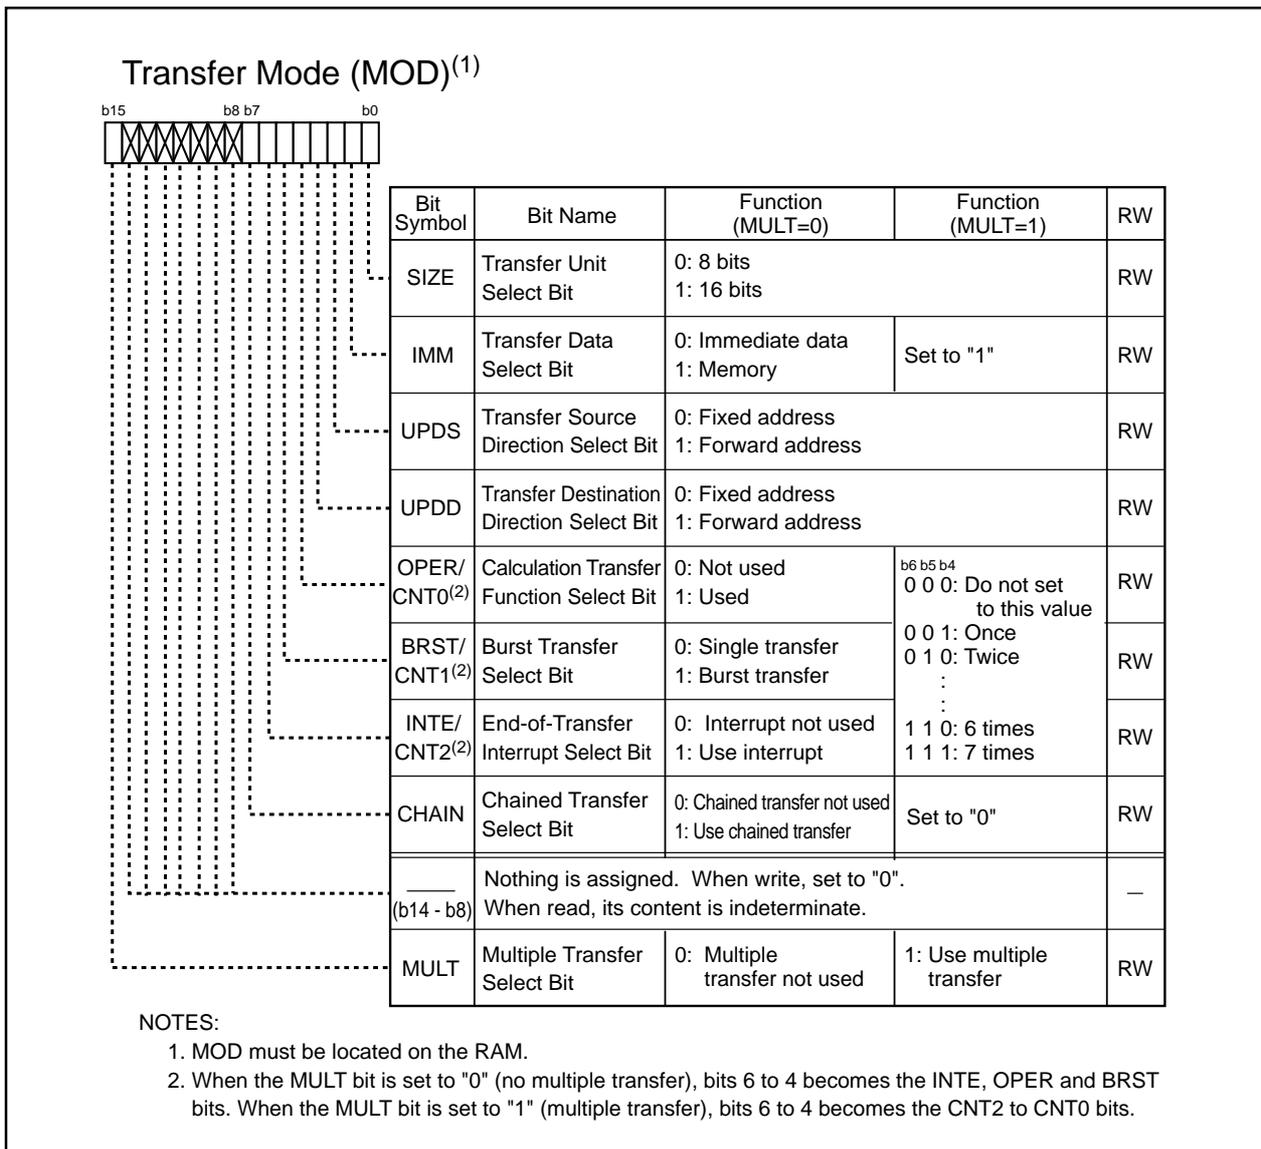

Figure 13.3 MOD

13.1.3 Interrupt Control Register for the Peripheral Function

For the peripheral function interrupt activating DMAC II, set the ILVL2 to ILVL0 bits to "1112" (level 7).

13.1.4 Relocatable Vector Table for the Peripheral Function

Set the starting address of the DMAC II index in the interrupt vector for the peripheral function interrupt activating DMAC II.

When using the chained transfer, the relocatable vector table must be located in the RAM.

13.1.5 IRLT Bit in the IIOiE Register (i=0 to 4)

When the intelligent I/O interrupt or CAN interrupt is used to activate DMAC II, set the IRLT bit in the IIOiE register of the interrupt to "0".

13.2 DMAC II Performance

Function to activate DMAC II is selected by setting the DMA II bit to "1" (DMAC II transfer). DMAC II is activated by all peripheral function interrupts with the ILVL2 to ILVL0 bits set to "1112" (level 7). These peripheral function interrupt request signals become DMAC II transfer request signals and the peripheral function interrupt cannot be used.

When an interrupt request is generated by setting the ILVL2 to ILVL0 bits to "1112" (level 7), DMAC II is activated regardless of what state the I flag and IPL are in.

13.3 Transfer Data

DMAC II transfers 8-bit or 16-bit data.

- Memory-to-memory transfer : Data is transferred from a desired memory location in a 64-Kbyte space (Addresses 00000₁₆ to 0FFFF₁₆) to another desired memory location in the same space.
- Immediate data transfer : Immediate data is transferred to a desired memory location in a 64-Kbyte space.
- Calculation transfer : Two 8-bit or 16-bit data are added together and the result is transferred to a desired memory location in a 64-Kbyte space.

When a 16-bit data is transferred to the destination address 0FFFF₁₆, it is transferred to 0FFFF₁₆ and 10000₁₆. The same transfer occurs when the source address is 0FFFF₁₆. Actual transferable space varies depending on the internal RAM capacity.

13.3.1 Memory-to-memory Transfer

Data transfer between any two memory locations can be:

- a transfer from a fixed address to another fixed address
- a transfer from a fixed address to a relocatable address
- a transfer from a relocatable address to a fixed address
- a transfer from a relocatable address to another relocatable address

When a relocatable address is selected, the address is incremented, after a transfer, for the next transfer. In a 8-bit transfer, the transfer address is incremented by one. In a 16-bit transfer, the transfer address is incremented by two.

When a source or destination address exceeds address 0FFFF₁₆ as a result of address incrementation, the source or destination address returns to address 00000₁₆ and continues incrementation. Maintain source and destination address at address 0FFFF₁₆ or below.

13.3.2 Immediate Data Transfer

DMAC II transfers immediate data to any memory location. A fixed or relocatable address can be selected as the destination address. Store the immediate data into SADR. To transfer an 8-bit immediate data, write the data in the low-order byte of SADR (high-order byte is ignored).

13.3.3 Calculation Transfer

After two memory data or an immediate data and memory data are added together, DMAC II transfers calculated result to any memory location. SADR must have one memory location address to be calculated or immediate data and OADR must have the other memory location address to be calculated. Fixed or relocatable address can be selected as source and destination addresses when using a memory + memory calculation transfer. If the transfer source address is relocatable, the operation address also becomes relocatable. Fixed or relocatable address can be selected as the transfer destination address when using an immediate data + memory calculation transfer.

13.4 Transfer Modes

Single and burst transfers are available. The BRST bit in MOD selects transfer method, either single transfer or burst transfer. COUNT determines how many transfers occur. No transfer occurs when COUNT is set to "0000₁₆".

13.4.1 Single Transfer

For every transfer request source, DMAC II transfers one transfer unit of 8-bit or 16-bit data once. When the source or destination address is relocatable, the address is incremented, after a transfer, for the next transfer.

COUNT is decremented every time a transfer occurs. When using the end-of-transfer interrupt, the interrupt is acknowledged when COUNT reaches "0".

13.4.2 Burst Transfer

For every transfer request source, DMAC II continuously transfers data the number of times determined by COUNT. COUNT is decremented every time a transfer occurs. The burst transfer ends when COUNT reaches "0". The end-of-transfer interrupt is acknowledged when the burst transfer ends if using the end-of-transfer interrupt. All interrupts are ignored while the burst transfer is in progress.

13.5 Multiple Transfer

The MULT bit in MOD selects the multiple transfer. When using the multiple transfer, select the memory-to-memory transfer. One transfer request source initiates multiple transfers. The CNT2 to CNT0 bits in MOD selects the number of transfers from "001₂" (once) to "111₂" (7 times). Do not set the CNT2 to CNT0 bits to "000₂".

The transfer source and destination addresses for each transfer must be allocated alternately in addresses following MOD and COUNT. When the multiple transfer is selected, the calculation transfer, burst transfer, end-of-transfer interrupt and chained transfer cannot be used.

13.6 Chained Transfer

The CHAIN bit in MOD selects the chained transfer.

The following process initiates the chained transfer.

- (1) Transfer, caused by a transfer request source, occurs according to the content of the DMAC II index. The vectors of the request source indicates where the DMAC II index is allocated. For each request, the BRST bit selects either single or burst transfer.
- (2) When COUNT reaches "0", the contents of CADR1 and CADR0 are written to the vector of the request source. When the INTE bit in MOD is set to "1", the end-of-transfer interrupt is generated simultaneously.
- (3) When the next DMAC II transfer request is generated, transfer occurs according to the contents of the DMAC II index indicated by the peripheral function interrupt vector rewritten in (2).

Figure 13.4 shows the relocatable vector and DMACII index when the chained transfer is in progress. For the chained transfer, the relocatable vector table must be located in the RAM.

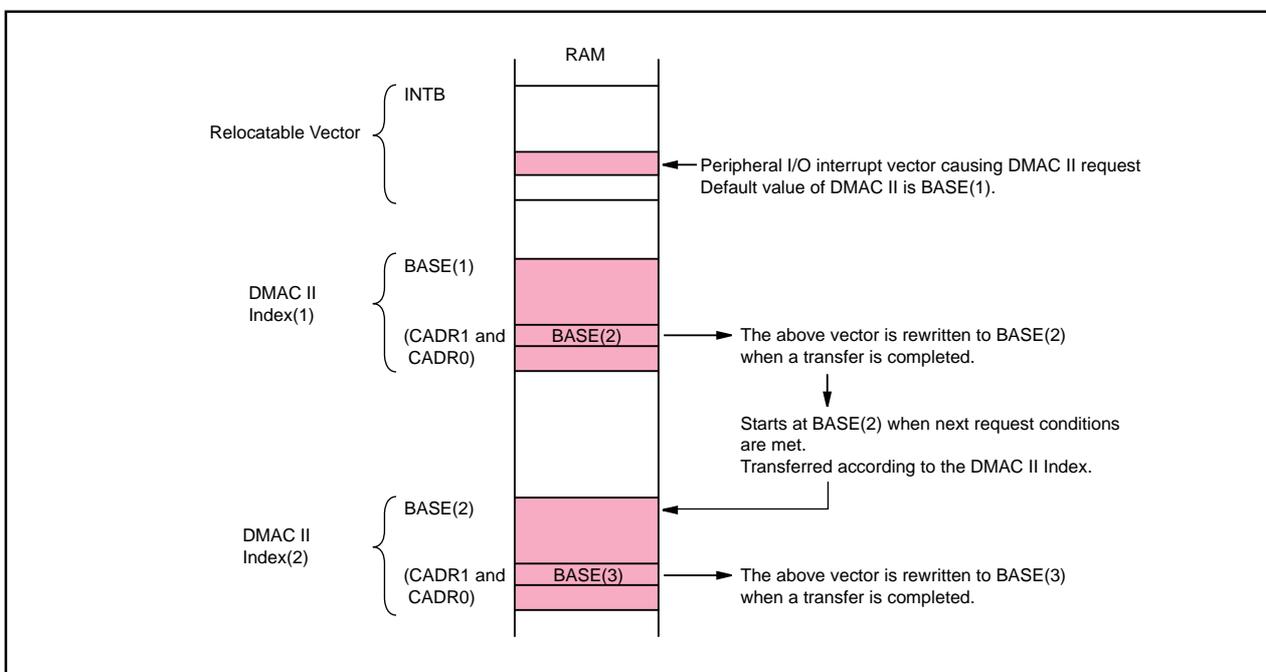

Figure 13.4 Relocatable Vector and DMAC II Index

13.7 End-of-Transfer Interrupt

The INTE bit in MOD selects the end-of-transfer interrupt. Set the starting address of the end-of-transfer interrupt routine in IADR1 and IADR0. The end-of-transfer interrupt is generated when COUNT reaches "0."

13.8 Execution Time

DMAC II execution cycle is calculated by the following equations:

Multiple transfers: $t = 21 + (11 + b + c) \times k$ cycles

Other than multiple transfers: $t = 6 + (26 + a + b + c + d) \times m + (4 + e) \times n$ cycles

a: If IMM = 0 (source of transfer is immediate data), a = 0;

if IMM = 1 (source of transfer is memory), a = -1

b: If UPDS = 1 (source transfer address is a relocatable address), b = 0;

if UPDS = 0 (source transfer address is a fixed address), b = 1

c: If UPDD = 1 (destination transfer address is a relocatable address), c = 0;

if UPDD = 0 (destination transfer address is a fixed address), c = 1

d: If OPER = 0 (calculation function is not selected), d = 0;

if OPER = 1 (calculation function is selected) and UPDS = 0 (source of transfer is immediate data or fixed address memory), d = 7;

if OPER = 1 (calculation function is selected) and UPDS = 1 (source of transfer is relocatable address memory), d = 8

e: If CHAIN = 0 (chained transfer is not selected), e = 0; if CHAIN = 1 (chained transfer is selected), e = 4

m: BRST = 0 (single transfer), m = 1; BRST = 1 (burst transfer), m = the value set in transfer counter

n: If COUNT = 1, n = 0; if COUNT = 2 or more, n = 1

k: Number of transfers set in the CNT2 to CNT0 bits

The equations above are approximations. The number of cycles may vary depending on CPU state, bus wait state, and DMAC II index allocation.

The first instruction from the end-of-transfer interrupt routine is executed in the eighth cycle after the DMAC II transfer is completed.

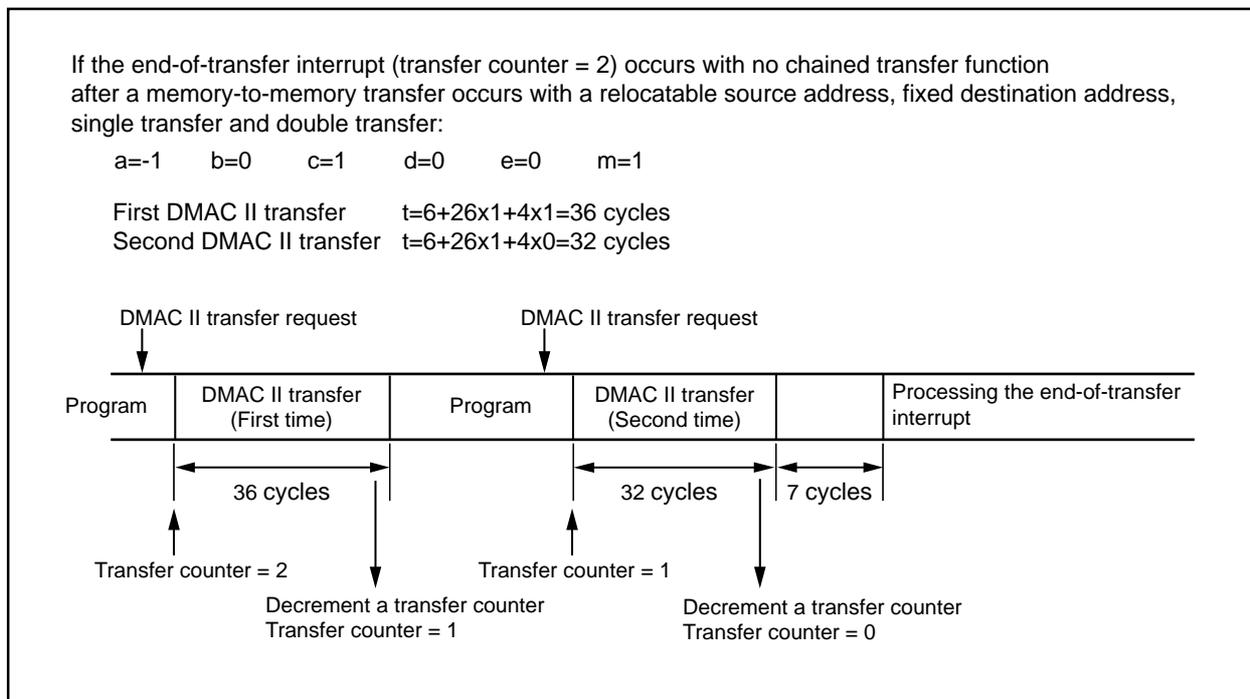

Figure 13.5 Transfer Cycle

When an interrupt request as a DMAC II transfer request source and another interrupt request with higher priority (e.g., $\overline{\text{NMI}}$ or watchdog timer) are generated simultaneously, the interrupt with higher priority takes precedence over the DMAC II transfer. The pending DMAC II transfer starts after the interrupt sequence has been completed.

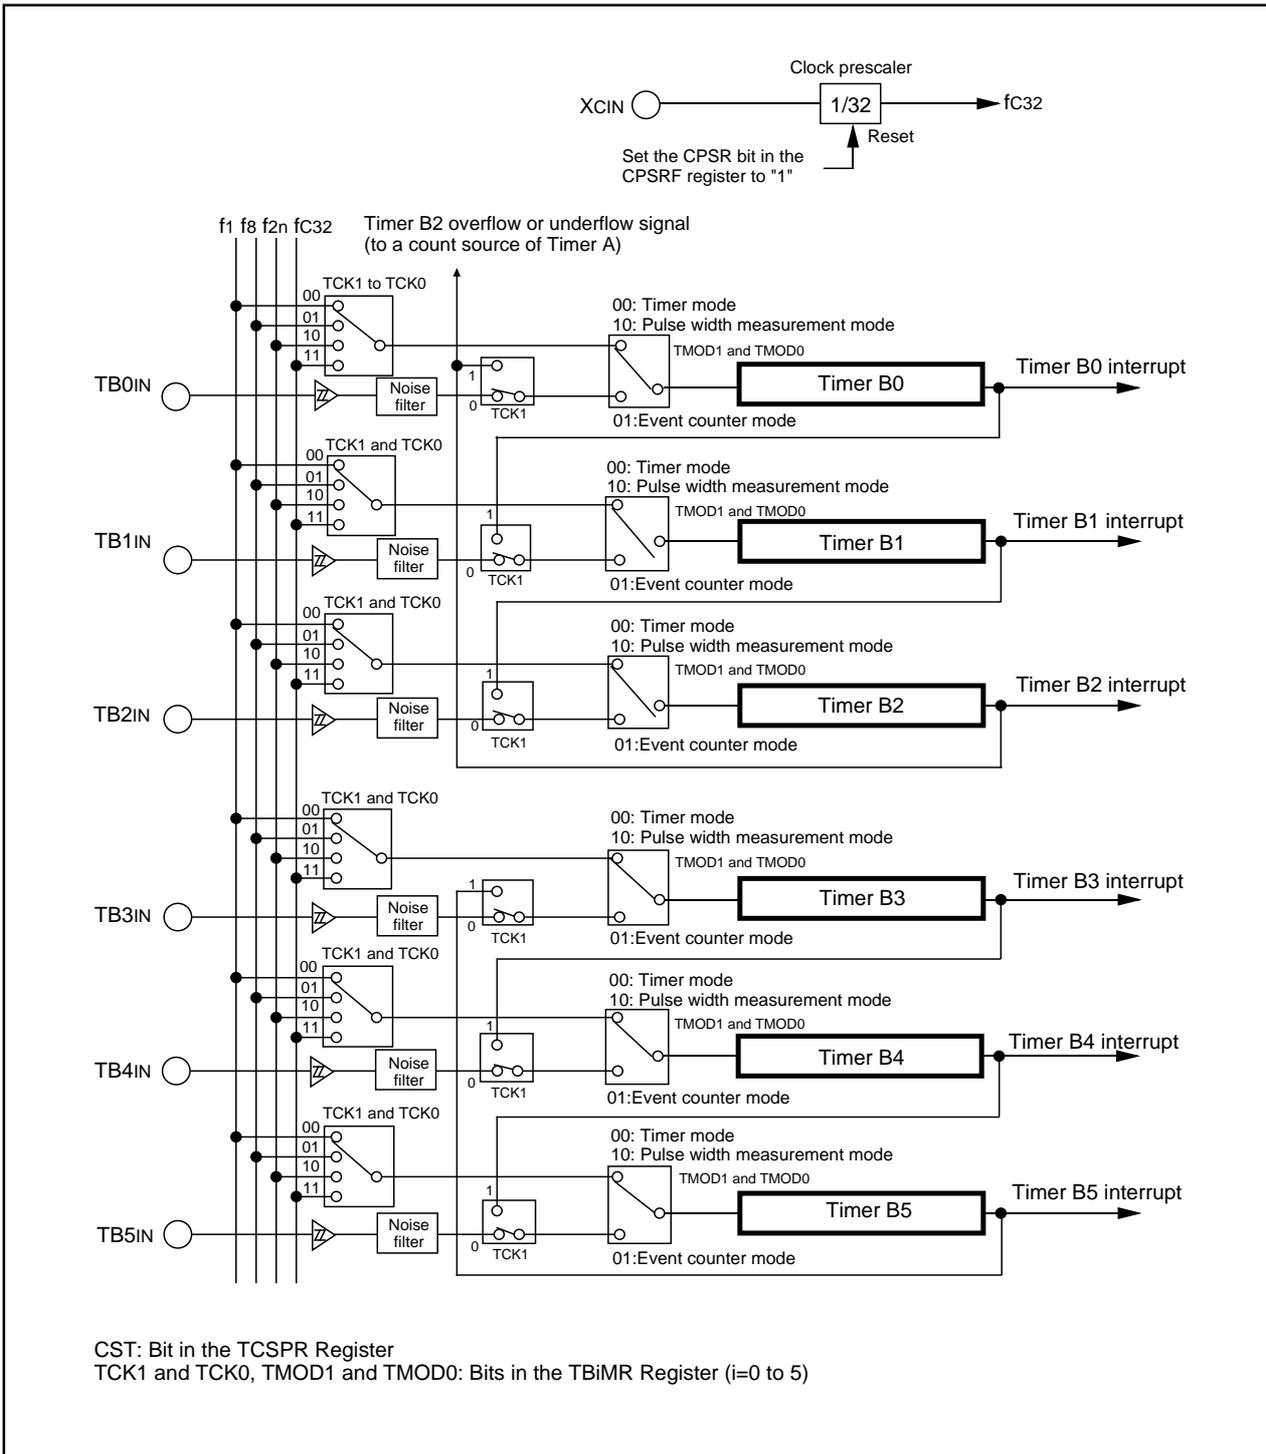

Figure 14.2 Timer B Configuration

14.1 Timer A

Figure 14.3 shows a block diagram of the timer A. Figures 14.4 to 14.7 show registers associated with the timer A.

The timer A supports the following four modes. Except in event counter mode, all timers A0 to A4 have the same function. The TMOD1 and TMOD0 bits in the TAI_{MR} register (i=0 to 4) determine which mode is used.

- Timer mode: The timer counts an internal count source.
- Event counter mode: The timer counts an external pulse or an overflow and underflow of other timers.
- One-shot timer mode: The timer outputs one valid pulse until a counter value reaches "000016".
- Pulse width modulation mode: The timer continuously outputs desired pulse widths.

Table 14.1 lists TAI_{OUT} pin settings when used as an output. Table 14.2 lists TAI_{IN} and TAI_{OUT} pin settings when used as an input.

TMOD0	Operating Mode Select Bit	b1b0 0 1: Event counter mode ⁽¹⁾			RW
TMOD1					RW
(b2)	Reserved Bit	Set to "0"			RW
MR1	Count Polarity Select Bit ⁽²⁾	0: Counts falling edges of an external signal 1: Counts rising edges of an external signal	Set to "0"		RW
MR2	Increment/Decrement Switching Source Select Bit	0: UDF register setting 1: Input signal to TAIOUT pin ⁽³⁾	Set to "1"		RW
MR3	Set to "0" in event counter mode				RW
TCK0	Count Operation Type Select Bit	0: Reloading 1: Free running			RW
TCK1	Two-Phase Pulse Signal Processing Operation Select Bit ^(4,5)	Set to "0"	0: Normal processing operation 1: Multiply-by-4 processing operation		RW

NOTES:

- The TAI_{TGH} and TAI_{TGL} bits in the ONSF or TRGSR register determine the count source in the event counter mode.
- MR1 bit setting is enabled only when counting how many times external signals are applied.
- The timer decrements a counter value when an "L" signal is applied to the TAI_{OUT} pin and the timer increments a counter value when an "H" signal is applied to the TAI_{OUT} pin.
- The TCK1 bit is enabled only in the TA3MR register.
- For two-phase pulse signal processing, set the TAJ_P bit in the UDF register (j=2 to 4) to "1" (two-phase pulse signal processing function enabled). Also, set the TAJ_{TGH} and TAJ_{TGL} bits to "002" (input to the TAJ_{IN} pin).

Figure 14.9 TA0MR to TA4MR Registers

14.1.2.1 Counter Reset by Two-Phase Pulse Signal Processing

Z-phase input resets the timer counter when processing a two-phase pulse signal.

This function can be used in timer A3 event counter mode, two-phase pulse signal processing, free-running count operation type or multiply-by-4 processing. The Z-phase signal is applied to the $\overline{\text{INT2}}$ pin. When the TAZIE bit in the ONSF register is set to "1" (Z-phase input enabled), Z-phase input can reset the timer counter. To reset the counter by a Z-phase input, set the TA3 register to "000016" beforehand.

Z-phase input is enabled when the edge of the signal applied to the $\overline{\text{INT2}}$ pin is detected. The POL bit in the INT2IC register can determine edge polarity. The Z-phase must have a pulse width of one timer A3 count source cycle or more. Figure 14.10 shows two-phase pulses (A-phase and B-phase) and the Z-phase.

Z-phase input resets the timer counter in the next count source following Z-phase input. Figure 14.11 shows the counter reset timing.

Timer A3 interrupt request is generated twice continuously when a timer A3 overflow or underflow, and a counter reset by $\overline{\text{INT2}}$ input occur at the same time. Do not use the timer A3 interrupt request when this function is used.

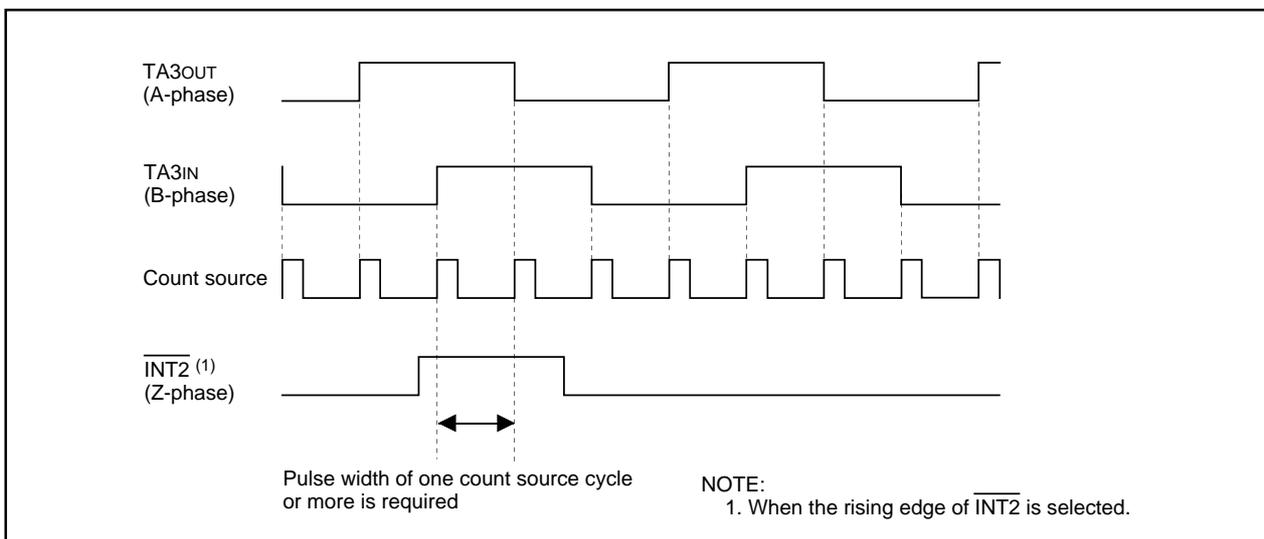

Figure 14.10 Two-Phase Pulse (A-phase and B-phase) and Z-phase

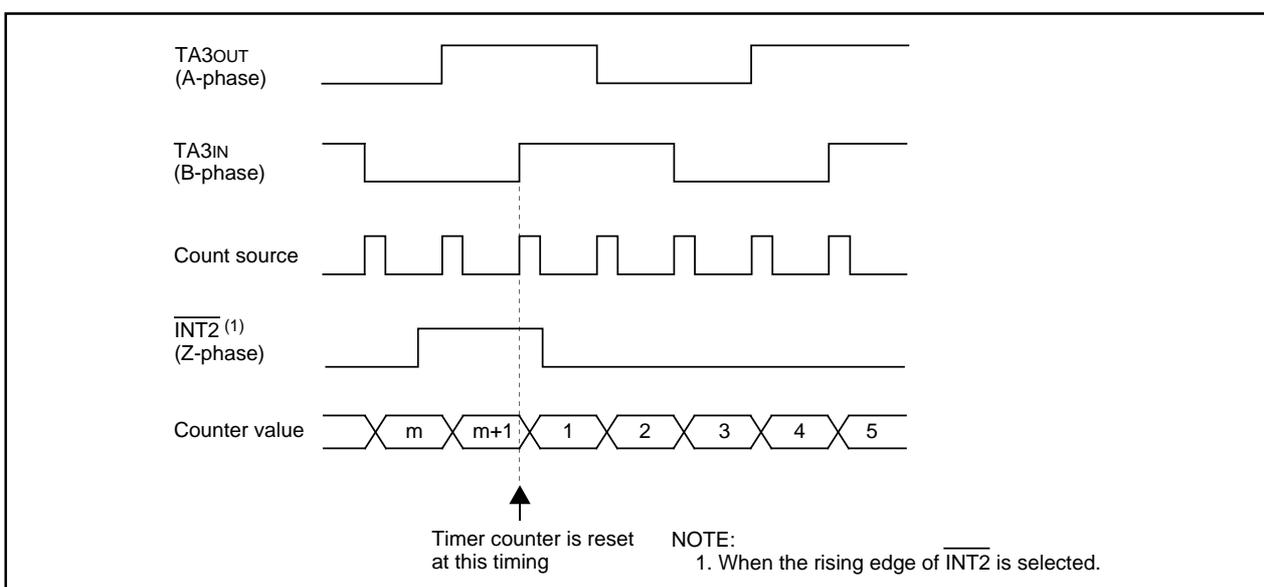

Figure 14.11 Counter Reset Timing

14.1.3 One-Shot Timer Mode

In one-shot timer mode, the timer operates only once for each trigger (see **Table 14.6**). Once a trigger occurs, the timer starts and continues operating for a desired period. Figure 14.12 shows the TAI_MR register (i=0 to 4) in one-shot timer mode.

Table 14.6 One-Shot Timer Mode Specifications

Item	Specification
Count Source	f ₁ , f ₈ , f _{2n} ⁽¹⁾ , f _{C32}
Counting Operation	<ul style="list-style-type: none"> The timer decrements a counter value When the timer counter reaches "0000 ₁₆ ", it stops counting after reloading. If a trigger occurs while counting, content of the reload register is reloaded into the count register and counting resumes.
Divide Ratio	1/n n: setting value of the TAI register (i=0 to 4) 0000 ₁₆ to FFFF ₁₆ , but the timer counter does not run if n=0000 ₁₆
Counter Start Condition	The TAI _S bit in the TABSR register is set to "1" (starts counting) and following triggers occur: <ul style="list-style-type: none"> External trigger input is provided Timer counter overflows or underflows The TAI_{OS} bit in the ONSF register is set to "1" (timer started)
Counter Stop Condition	<ul style="list-style-type: none"> After the timer counter has reached "0000₁₆" and is reloaded When the TAI_S bit is set to "0" (stops counting)
Interrupt Request Generation Timing	The timer counter reaches "0000 ₁₆ "
TAI _{IN} Pin Function	Programmable I/O port or trigger input
TAI _{OUT} Pin Function	Programmable I/O port or pulse output
Read from Timer	The value in the TAI register is indeterminate when read
Write to Timer	<ul style="list-style-type: none"> When the timer counter stops, the value written to the TAI register is also written to both reload register and counter While counting, the value written to the TAI register is written to the reload register (It is transferred to the counter at the next reload timing)

NOTE:

- The CNT3 to CNT0 bits in the TCSPR register select no division (n=0) or divide-by-2n (n=1 to 15).

14.2 Timer B

Figure 14.16 shows a block diagram of the timer B. Figures 14.17 to 14.19 show registers associated with the timer B. The timer B supports the following three modes. The TMOD1 and TMOD0 bits in the TBiMR register ($i=0$ to 5) determine which mode is used.

- Timer mode : The timer counts an internal count source.
- Event counter mode : The timer counts pulses from an external source or overflow and underflow of another timer.
- Pulse period/pulse width measurement mode : The timer measures pulse period or pulse width of an external signal.

Table 14.8 lists TBiIN pin settings.

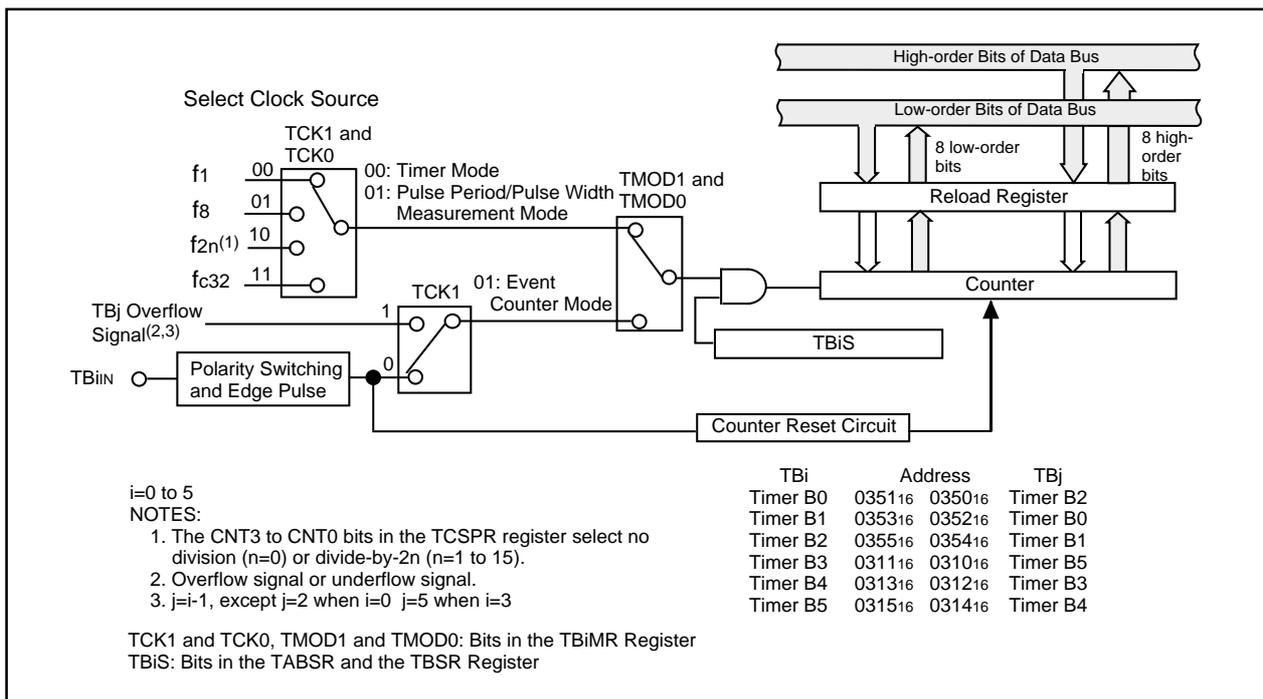

Figure 14.16 Timer B Block Diagram

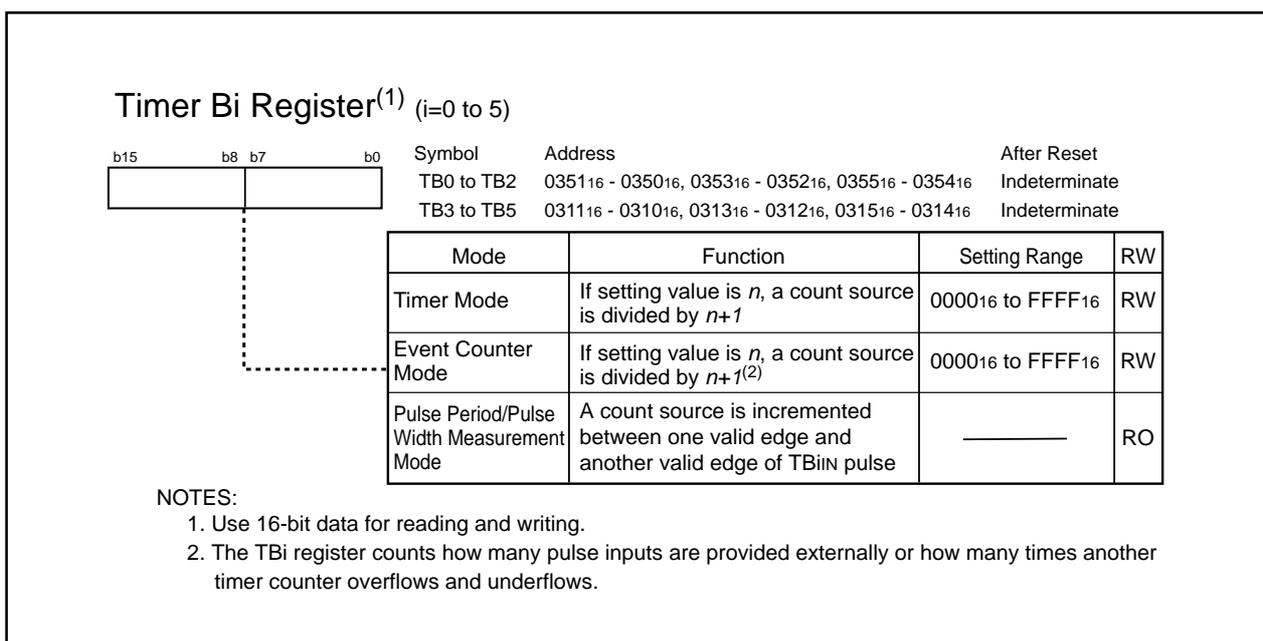

Figure 14.17 TB0 to TB5 Registers

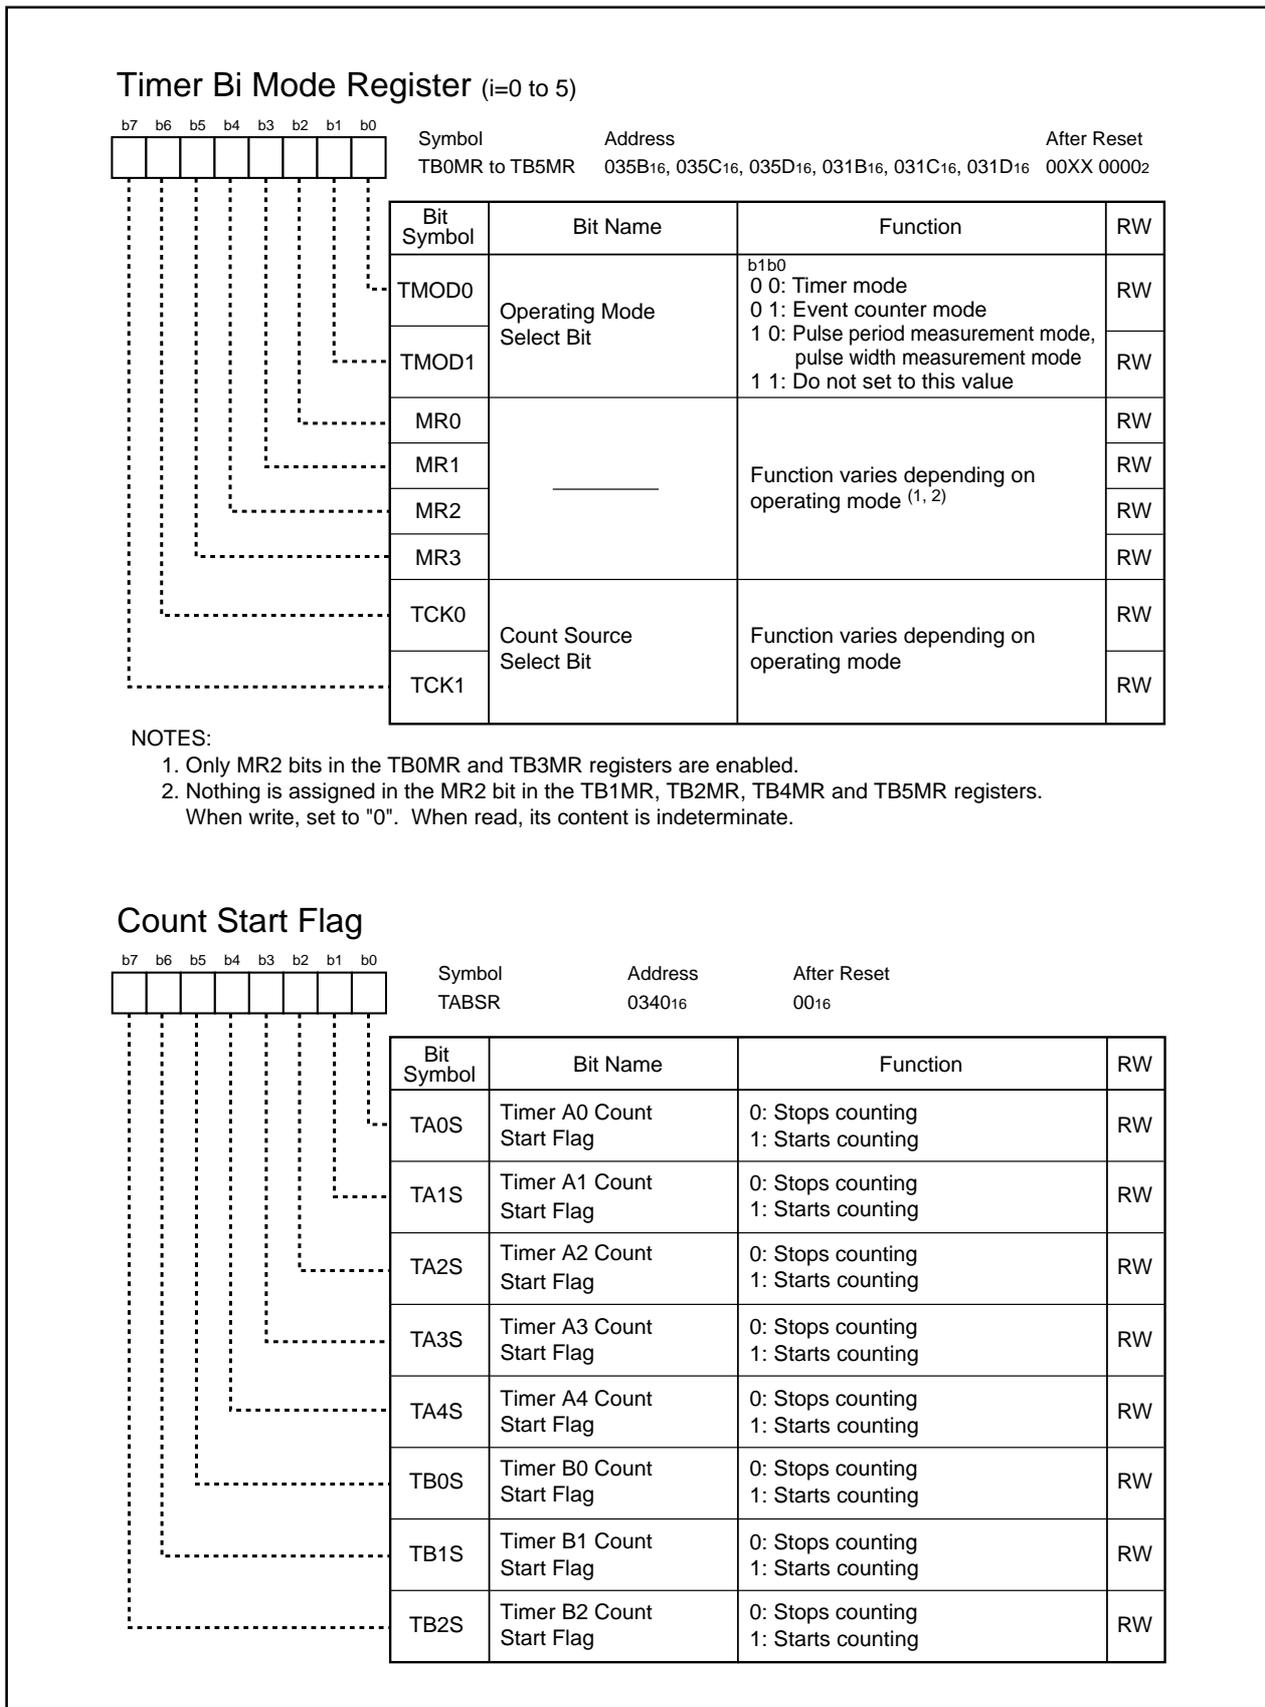

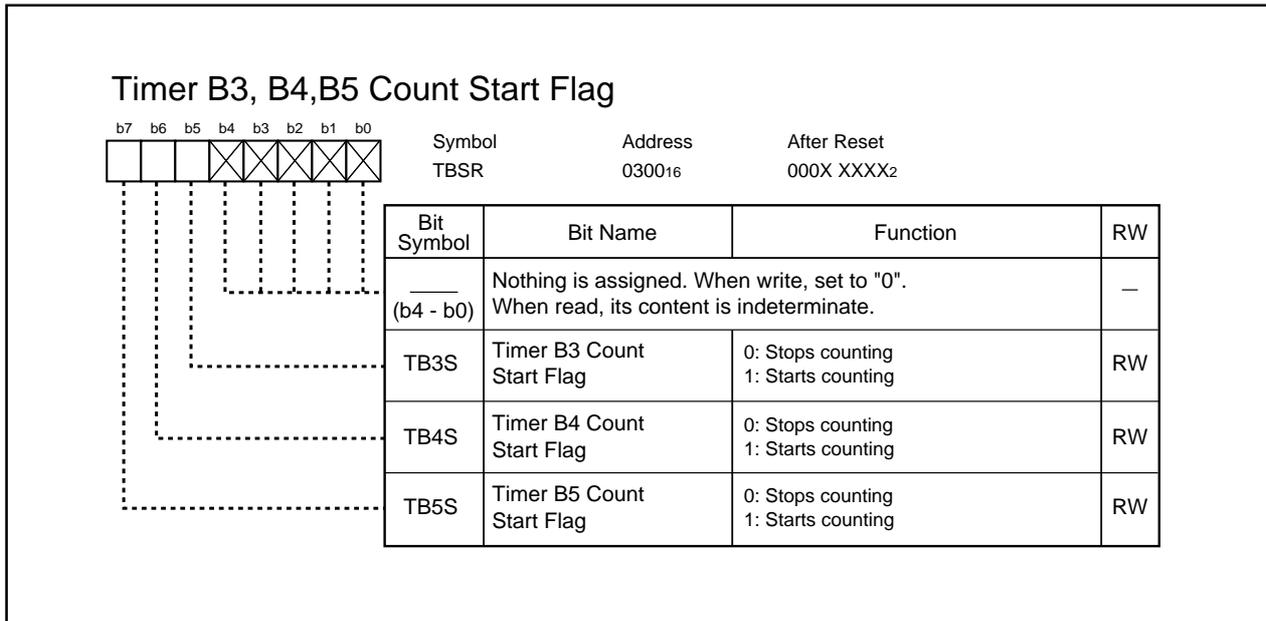

Figure 14.18 TB0MR to TB5MR Registers, TABSR Register

**Figure 14.19 TBSR Register****Table 14.8 Settings for the TB*i*N Pins (i=0 to 5)**

Port Name	Function	Setting	
		PS1, PS3 ⁽¹⁾ Registers	PD7, PD9 ⁽¹⁾ Registers
P90	TB0IN	PS3_0=0	PD9_0=0
P91	TB1IN	PS3_1=0	PD9_1=0
P92	TB2IN	PS3_2=0	PD9_2=0
P93	TB3IN	PS3_3=0	PD9_3=0
P94	TB4IN	PS3_4=0	PD9_4=0
P71	TB5IN	PS1_1=0	PD7_1=0

NOTE:

- Set the PD9 and PS3 registers immediately after the PRC2 bit in the PRCR register is set to "1" (write enabled). Do not generate an interrupt or a DMA transfer between the instruction to set the PRC2 bit to "1" and the instruction to set the PD9 and PS3 registers.

14.2.1 Timer Mode

In timer mode, the timer counts an internally generated count source (see **Table 14.9**). Figure 14.20 shows the TBiMR register (i=0 to 5) in timer mode.

Table 14.9 Timer Mode Specifications

Item	Specification
Count Source	f1, f8, f2n ⁽¹⁾ , fc32
Counting Operation	<ul style="list-style-type: none"> The timer decrements a counter value When the timer counter underflows, content of the reload register is reloaded into the count register and counting resumes
Divide Ratio	$1/(n+1)$ <i>n</i> : setting value of the TBi register (i=0 to 5) 0000 ₁₆ to FFFF ₁₆
Counter Start Condition	The TBiS bits in the TABSR and TBSR registers are set to "1" (starts counting)
Counter Stop Condition	The TBiS bit is set to "0" (stops counting)
Interrupt Request Generation Timing	Timer counter underflows
TBiIn Pin Function	Programmable I/O port
Read from Timer	The TBi register indicates counter value
Write to Timer	<ul style="list-style-type: none"> When the timer counter stops, the value written to the TBi register is also written to both reload register and counter While counting, the value written to the TBi register is written to the reload register (It is transferred to the counter at the next reload timing)

NOTE:

- The CNT3 to CNT0 bits in the TCSPR register select no division (n=0) or divide-by-2n (n=1 to 15).

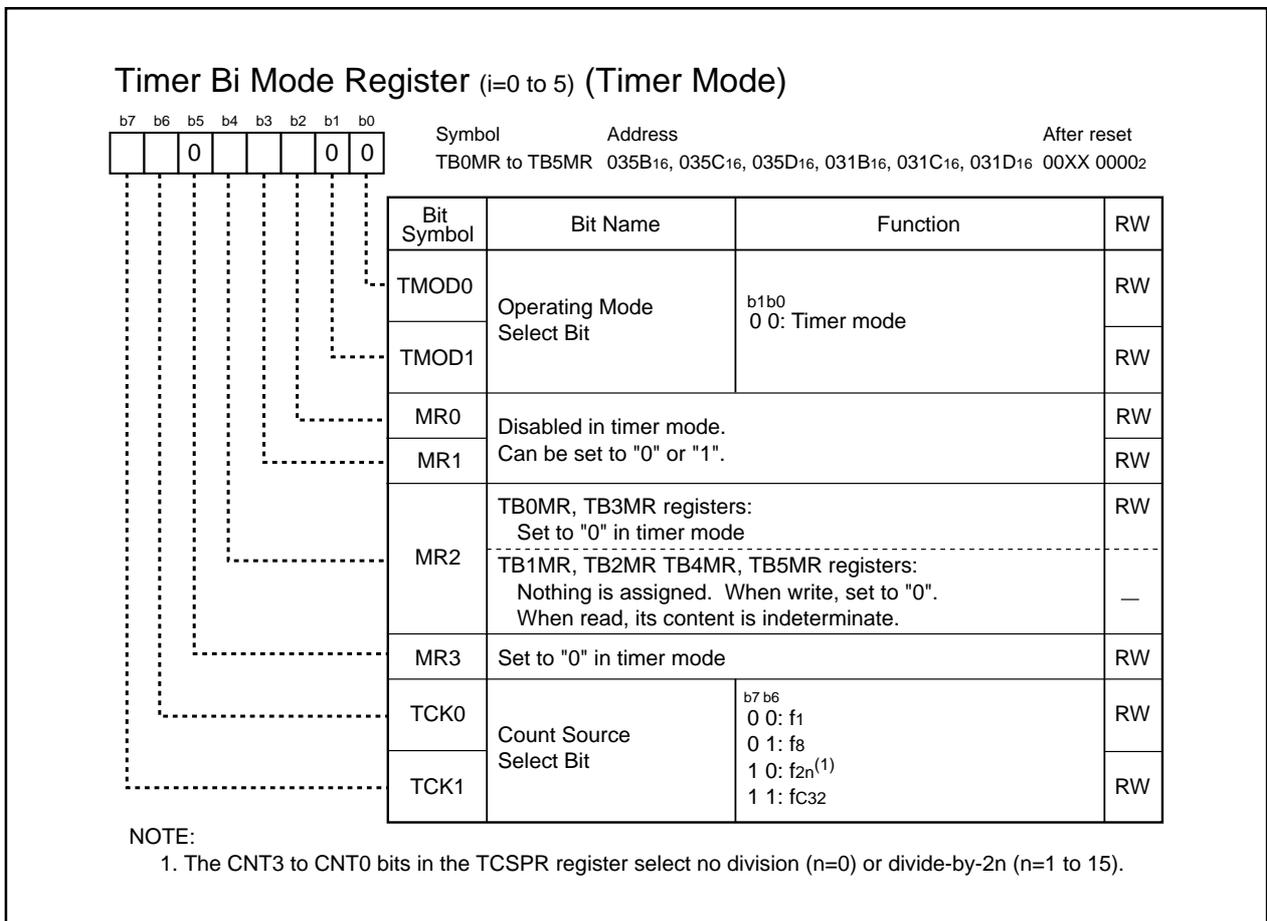

Figure 14.20 TB0MR to TB5MR Registers

14.2.2 Event Counter Mode

In event counter mode, the timer counts how many external signals are applied or how many times another timer overflows and underflows. (See **Table 14.10**) Figure 14.21 shows the TBiMR register (i=0 to 5) in event counter mode.

Table 14.10 Event Counter Mode Specifications

Item	Specification
Count Source	<ul style="list-style-type: none"> External signal applied to the TBiIN pin (i = 0 to 5) (valid edge can be selected by program) TBj overflow or underflow signal (j=i-1, except j=2 when i=0, j=5 when i=3)
Counting Operation	<ul style="list-style-type: none"> The timer decrements a counter value When the timer counter underflows, content of the reload register is reloaded into the count register to continue counting
Divide Ratio	$1/(n+1)$ n : setting value of the TBi register 0000 ₁₆ to FFFF ₁₆
Counter Start Condition	The TBiS bits in the TABSR and TBSR register are set to "1" (starts counting)
Counter Stop Condition	The TBiS bit is set to "0" (stops counting)
Interrupt Request Generation Timing	The timer counter underflows
TBiIN Pin Function	Programmable I/O port or count source input
Read from Timer	The TBi register indicates counter value
Write to Timer	<ul style="list-style-type: none"> When the timer counter stops, the value written to the TBi register is also written to both reload register and counter While counting, the value written to the TBi register is written to the reload register (It is transferred to the counter at the next reload timing)

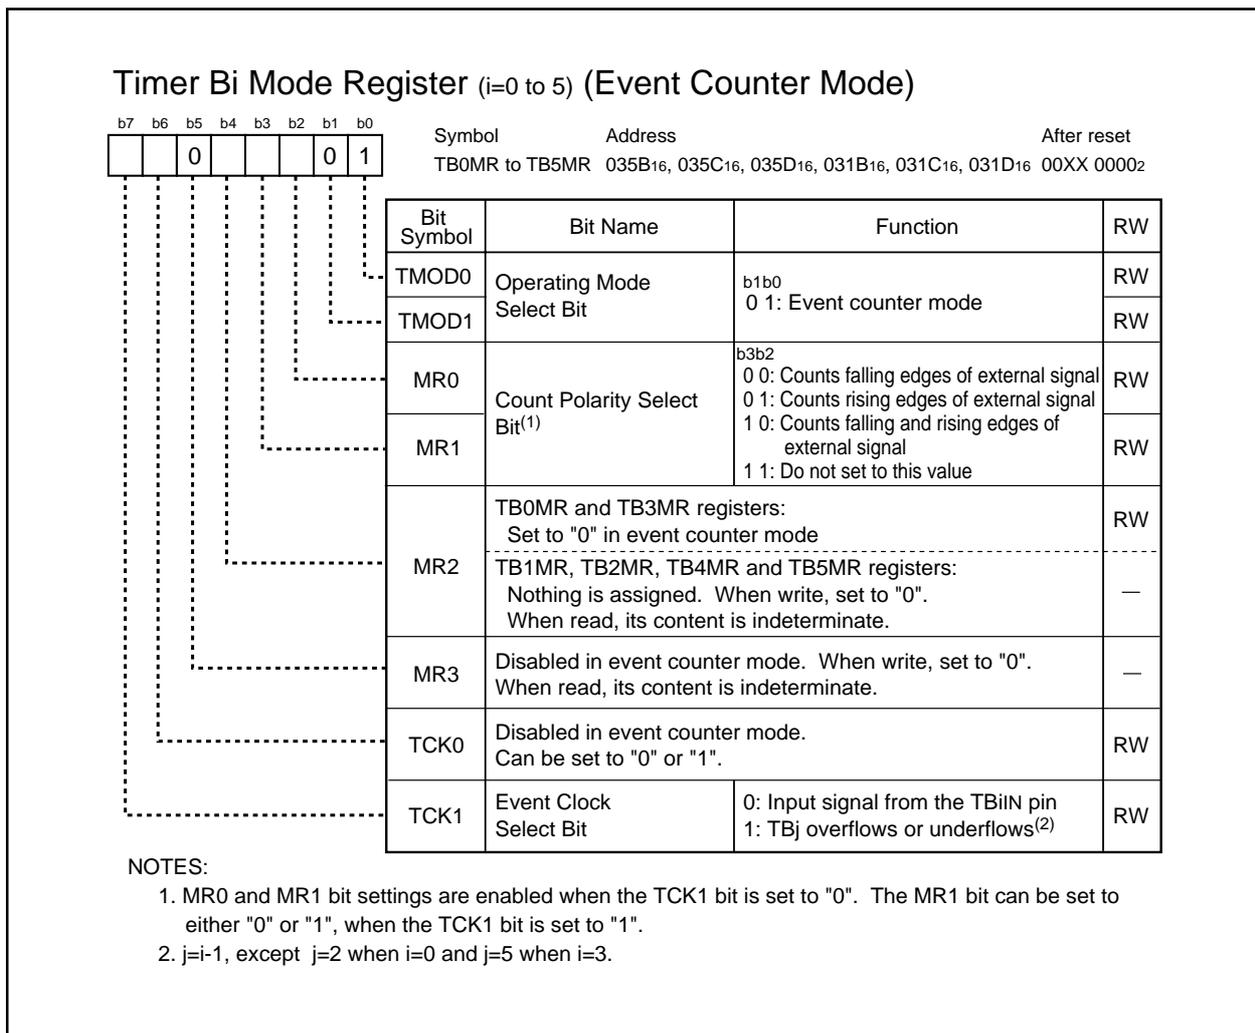

Figure 14.21 TB0MR to TB5MR Registers

14.2.3 Pulse Period/Pulse Width Measurement Mode

In pulse period/pulse width measurement mode, the timer measures pulse period or pulse width of an external signal. (See **Table 14.11**) Figure 14.22 shows the TBiMR register (i=0 to 5) in pulse period/pulse width measurement mode. Figure 14.23 shows an operation example in pulse period measurement mode. Figure 14.24 shows an operation example in the pulse width measurement mode.

Table 14.11 Pulse Period/Pulse Width Measurement Mode Specifications

Item	Specification
Count Source	f1, f8, f2n ⁽³⁾ , fc32
Counting Operation	<ul style="list-style-type: none"> The timer increments a counter value Counter value is transferred to the reload register on the valid edge of a pulse to be measured. It is set to "000016" and the timer continues counting
Counter Start Condition	The TBiS bits (i=0 to 5) in the TABSR and TBSR register are set to "1" (starts counting)
Counter Stop Condition	The TBiS bit is set to "0" (stops counting)
Interrupt Request Generation Timing	<ul style="list-style-type: none"> On the valid edge of a pulse to be measured⁽¹⁾ The timer counter overflows The MR3 bit in the TBiMR register is set to "1" (overflow) simultaneously. When the TBiS bit is set to "1" (start counting) and the next count source is counted after setting the MR3 bit to "1" (overflow), the MR3 bit can be set to "0" (no overflow) by writing to the TBiMR register.
TBiIN Pin Function	Input for a pulse to be measured
Read from Timer	The TBi register indicates reload register values (measurement results) ⁽²⁾
Write to Timer	Value written to the TBi register can be written to neither reload register nor counter

NOTES:

1. No interrupt request is generated when the pulse to be measured is on the first valid edge after the timer has started counting.
2. The TBi register is in an indeterminate state until the pulse to be measured is on the second valid edge after the timer has started counting.
3. The CNT3 to CNT0 bits in the TCSPR register select no division (n=0) or divide-by-2n (n=1 to 15).

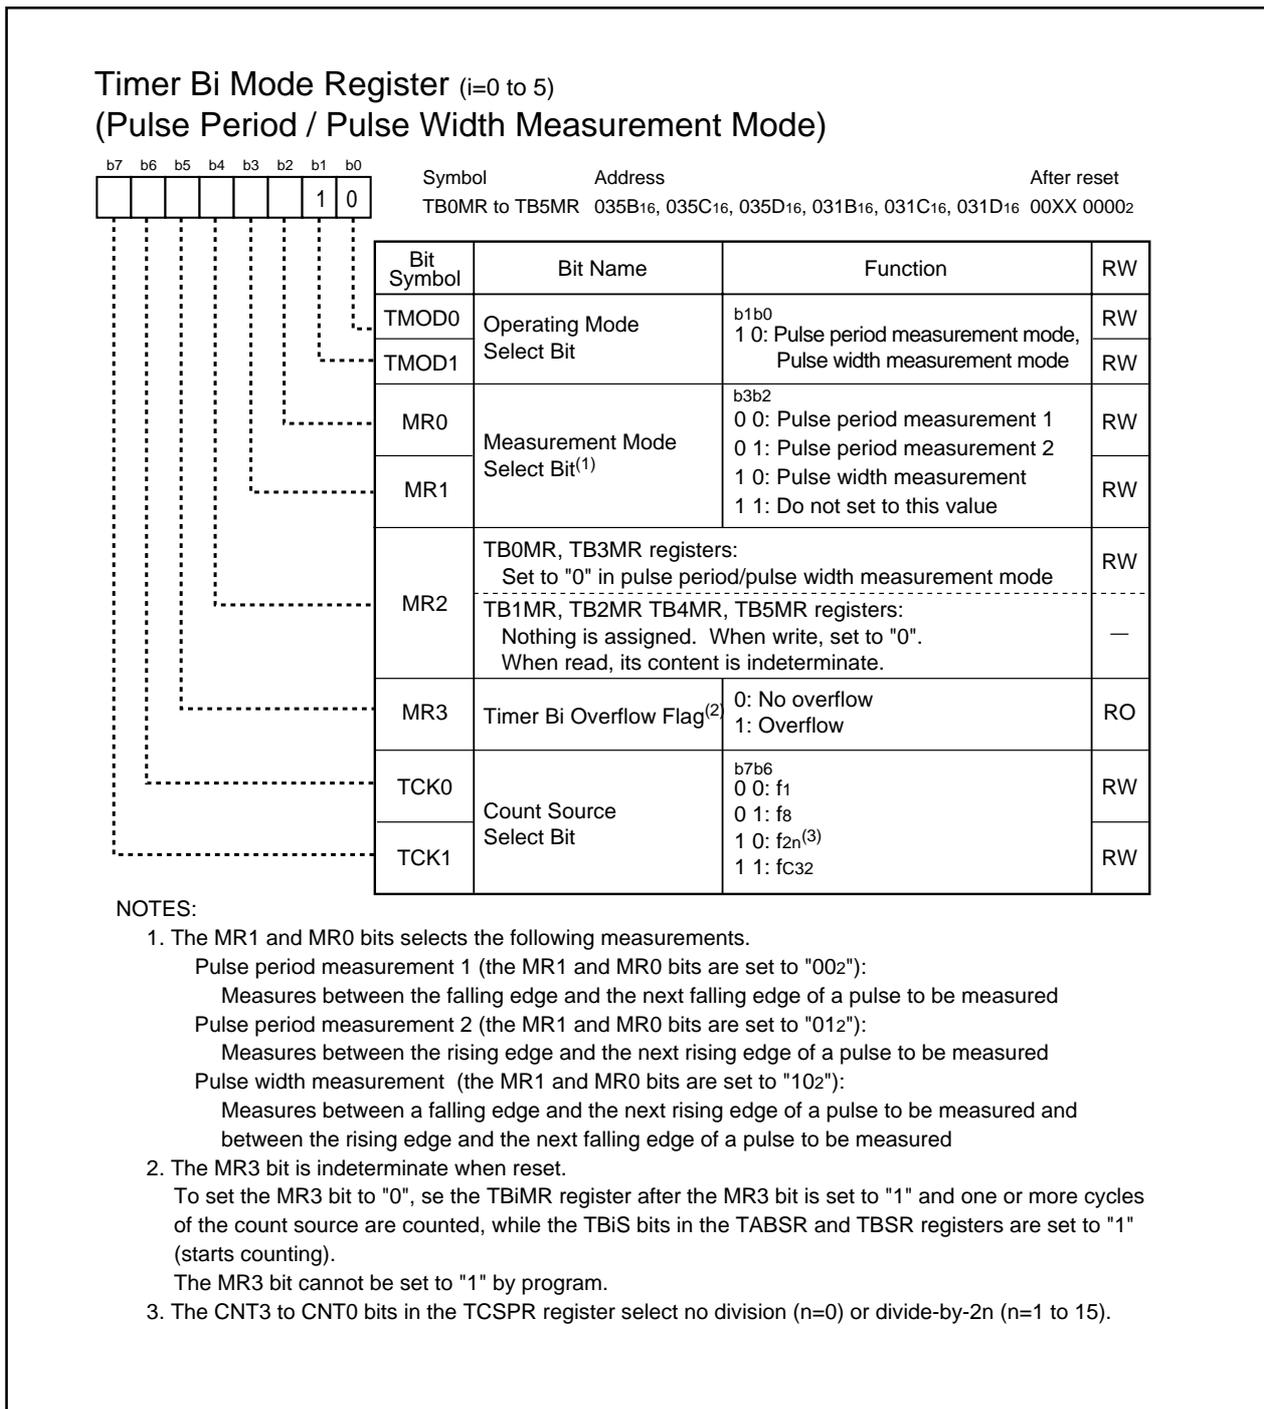

Figure 14.22 TB0MR to TB5MR Registers

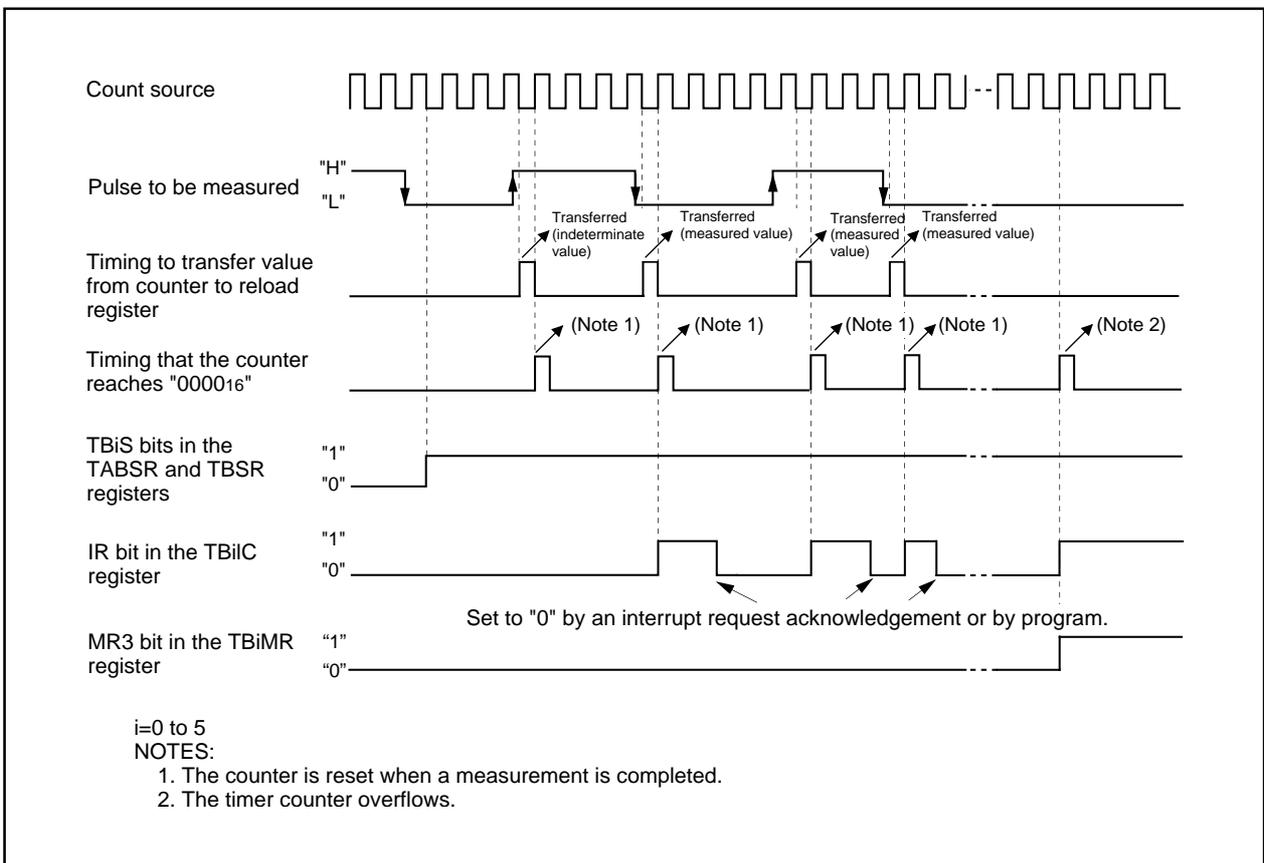

Figure 14.24 Operation Example in Pulse Width Measurement Mode

15. Three-Phase Motor Control Timer Functions

Three-phase motor driving waveform can be output by using the timers A1, A2, A4 and B2. Table 15.1 lists specifications of the three-phase motor control timer functions. Table 15.2 lists pin settings. Figure 15.1 shows a block diagram. Figures 15.2 to 15.7 show registers associated with the three-phase motor control timer functions.

Table 15.1 Three-Phase Motor Control Timer Functions Specification

Item	Specification
Three-Phase Waveform Output Pin	Six pins (U, \bar{U} , V, \bar{V} , W, \bar{W})
Forced Cutoff ⁽¹⁾	Apply a low-level ("L") signal to the NMI pin
Timers to be Used	Timer A4, A1, A2 (used in one-shot timer mode): Timer A4: U- and \bar{U} -phase waveform control Timer A1: V- and \bar{V} -phase waveform control Timer A2: W- and \bar{W} -phase waveform control Timer B2 (used in timer mode): Carrier wave cycle control Dead time timer (three 8-bit timers share reload register): Dead time control
Output Waveform	Triangular wave modulation, Sawtooth wave modulation Can output a high-level waveform or a low-level waveform for one cycle; Can set positive-phase level and negative-phase level separately
Carrier Wave Cycle	Triangular wave modulation: $count\ source \times (m+1) \times 2$ Sawtooth wave modulation: $count\ source \times (m+1)$ m : setting value of the TB2 register, 0000 ₁₆ to FFFF ₁₆ Count source: f_1 , f_8 , $f_{2n^{(2)}}$, f_{c32}
Three-Phase PWM Output Width	Triangular wave modulation: $count\ source \times n \times 2$ Sawtooth wave modulation: $count\ source \times n$ n : setting value of the TA4, TA1 and TA2 register (of the TA4, TA41, TA1, TA11, TA2 and TA21 registers when setting the INV11 bit to "1"), 0001 ₁₆ to FFFF ₁₆ Count source: f_1 , f_8 , $f_{2n^{(2)}}$, f_{c32}
Dead Time	$Count\ source \times p$, or no dead time p : setting value of the DTT register, 01 ₁₆ to FF ₁₆ Count source: f_1 , or f_1 divided by 2
Active Level	Selected from a high level ("H") or low level ("L")
Positive- and Negative-Phase Concurrent Active Disable Function	Positive and negative-phases concurrent active disable function Positive and negative-phases concurrent active detect function
Interrupt Frequency	For the timer B2 interrupt, one carrier wave cycle-to-cycle basis through 15 time- carrier wave cycle-to-cycle basis can be selected

NOTES:

1. Forced cutoff by the signal applied to the \overline{NMI} pin is available when the INV02 bit is set to "1" (three-phase motor control timer functions) and the INV03 bit is set to "1" (three-phase motor control timer output enabled).
2. The CNT3 to CNT0 bits in the TCSPPR register select no division (n=0) or divide-by-2n (n=1 to 15).

Table 15.2 Pin Settings

Pin	Setting		
	PS1, PS2 Registers ⁽¹⁾	PSL1, PSL2 Registers	PSC Register
P72/V	PS1_2 =1	PSL1_2 =0	PSC_2 =1
P73/ \bar{V}	PS1_3 =1	PSL1_3 =1	PSC_3 =0
P74/W	PS1_4 =1	PSL1_4 =1	PSC_4 =0
P75/ \bar{W}	PS1_5 =1	PSL1_5 =0	—
P80/U	PS2_0 =1	PSL2_0 =1	—
P81/ \bar{U}	PS2_1 =1	PSL2_1 =0	—

NOTE:

1. Set the PS1_5 to PS1_2 bits and PS2_1 and PS2_0 bits in the PS1 and PS2 registers to "1" after the INV02 bit is set to "1".

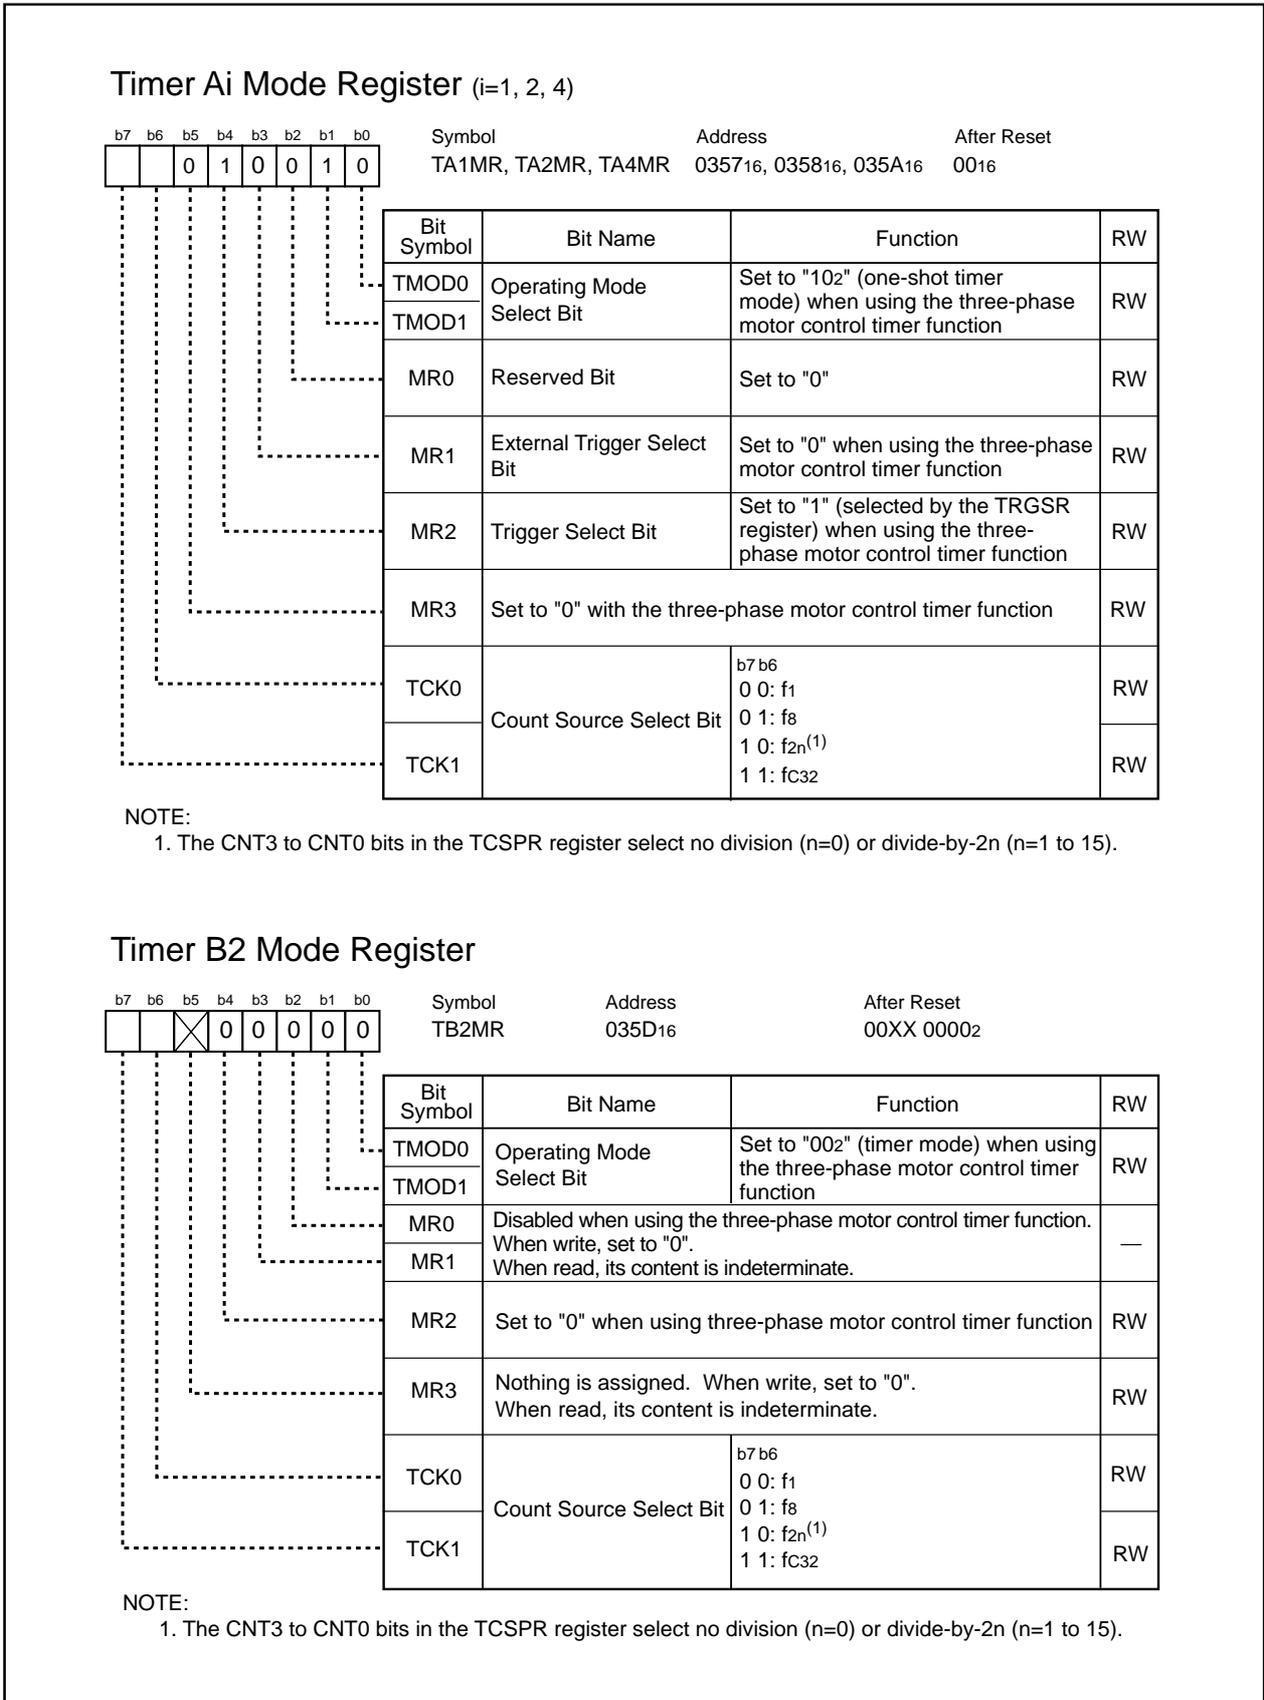

Figure 15.7 TA1MR, TA2MR and TA4MR Registers, TB2MR Register

The three-phase motor control timer function is available by setting the INV02 bit in the INVC0 register to "1". The timer B2 is used for carrier wave control and the timers A1, A2, A4 for three-phase PWM output (U, \bar{U} , V, \bar{V} , W, \bar{W}) control. An exclusive dead time timer controls dead time. Figure 15.8 shows an example of the triangular modulation waveform. Figure 15.9 shows an example of the sawtooth modulation waveform.

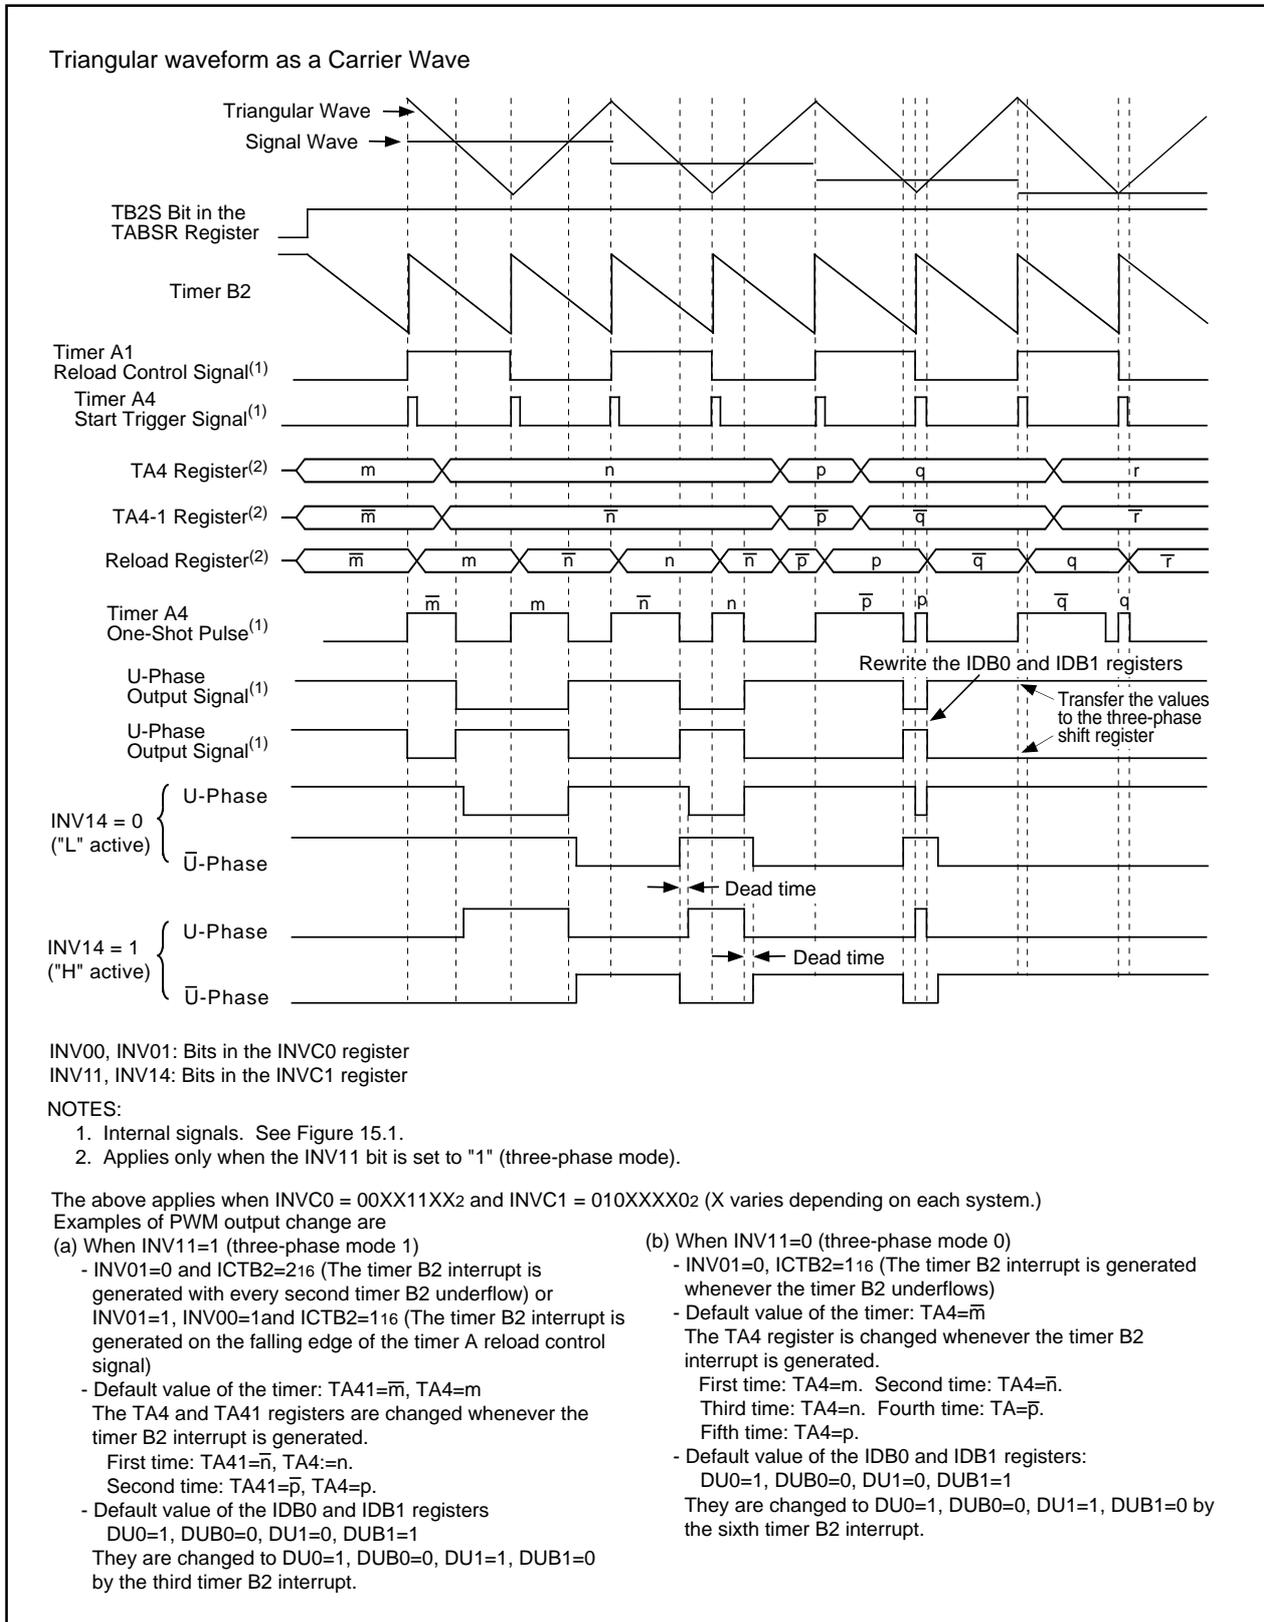

Figure 15.8 Triangular Wave Modulation Operation

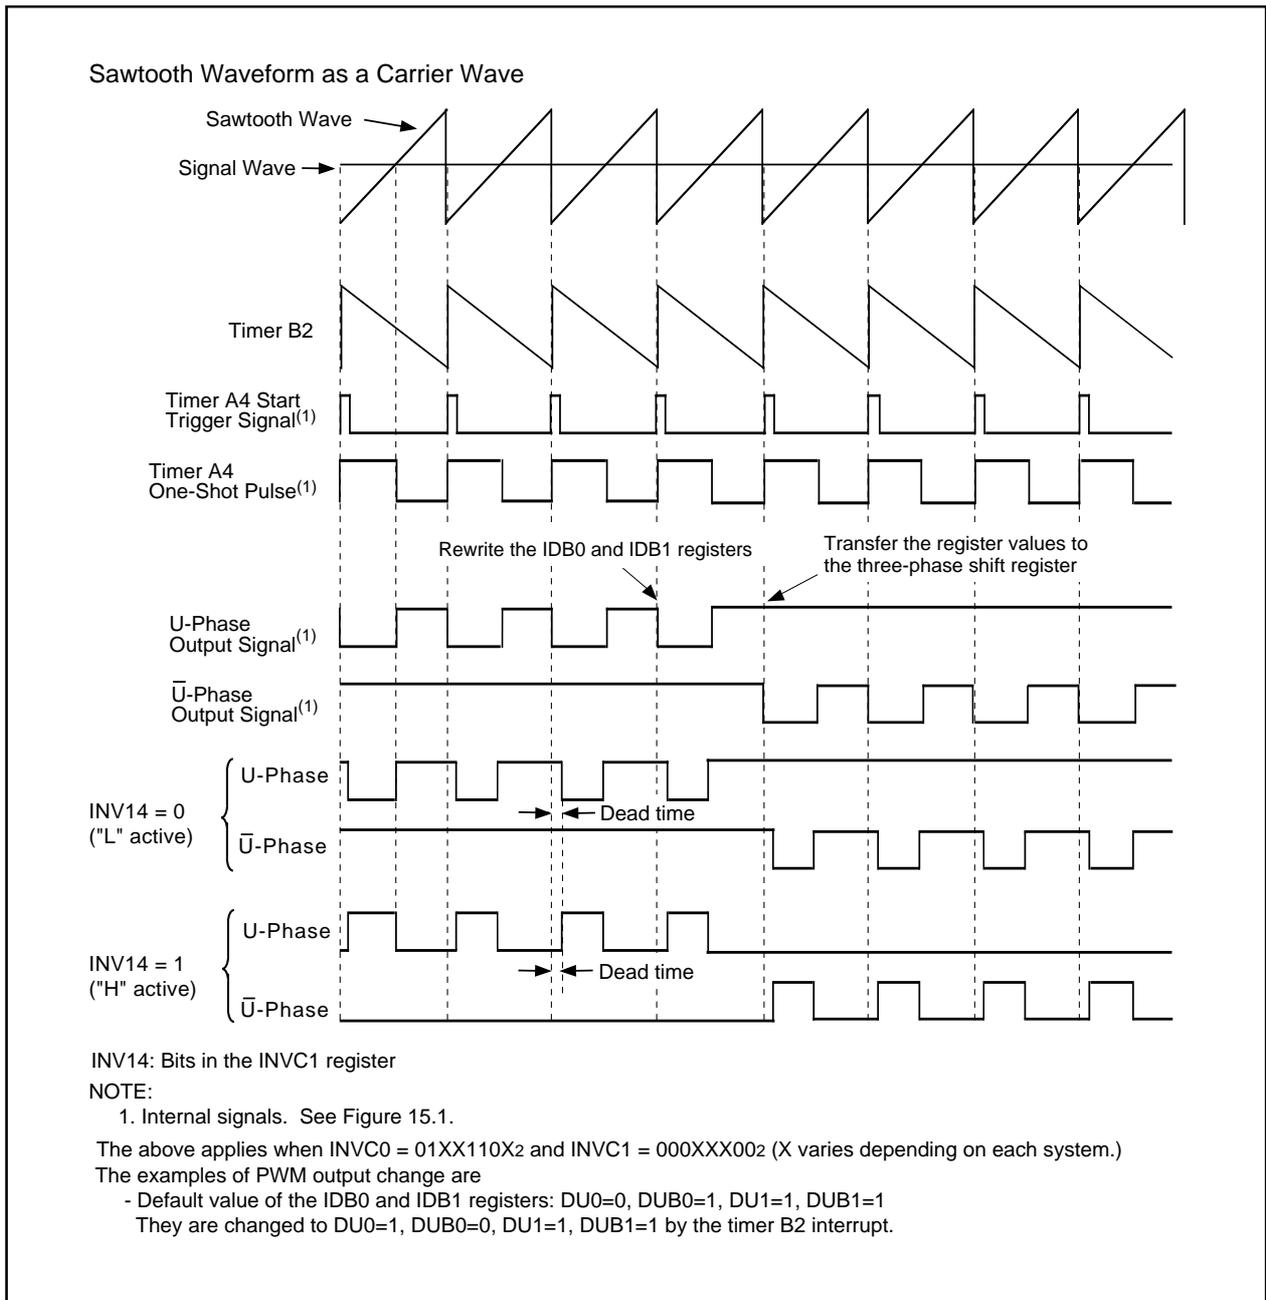

Figure 15.9 Sawtooth Wave Modulation Operation

16. Serial I/O

Serial I/O consists of five channels (UART0 to UART4).

Each UART_i (i=0 to 4) has an exclusive timer to generate the transfer clock and operates independently.

Figure 16.1 shows a UART_i block diagram.

UART_i supports the following modes :

- Clock synchronous serial I/O mode
- Clock asynchronous serial I/O mode (UART mode)
- Special mode 1 (I²C mode)
- Special mode 2
- Special mode 3 (Clock-divided synchronous function, GCI mode)
- Special mode 4 (Bus conflict detect function, IE mode)
- Special mode 5 (SIM mode)

Figures 16.2 to 16.9 show registers associated with UART_i.

Refer to the tables listing each mode for register and pin settings.

16.1 Clock Synchronous Serial I/O Mode

In clock synchronous serial I/O mode, data is transmitted and received with the transfer clock. Table 16.1 lists specifications of clock synchronous serial I/O mode. Table 16.2 lists register settings. Tables 16.3 to 16.5 list pin settings. When UART_i (i=0 to 4) operating mode is selected, the TxDi pin outputs a high-level ("H") signal before transfer starts (the TxDi pin is in a high-impedance state when the N-channel open drain output is selected). Figure 16.10 shows transmit and receive timings in clock synchronous serial I/O mode.

Table 16.1 Clock Synchronous Serial I/O Mode Specifications

Item	Specification
Transfer Data Format	Transfer data : 8 bits long
Transfer Clock	<ul style="list-style-type: none"> The CKDIR bit in the UiMR register (i=0 to 4) is set to "0" (internal clock selected): $\frac{f_j}{2^{(m+1)}} \quad f_j=f_1, f_8, f_{2^n(1)} \quad m:\text{setting value of the UiBRG register, } 00_{16} \text{ to } FF_{16}$ The CKDIR bit is set to "1" (external clock selected) : an input from the CLK_i pin
Transmit/Receive Control	Selected from the $\overline{\text{CTS}}$ function, RTS function or CTS/RTS function disabled
Transmit Start Condition	To start transmitting, the following requirements must be met ⁽²⁾ : <ul style="list-style-type: none"> - Set the TE bit in the UiC1 register to "1" (transmit enabled) - Set the TI bit in the UiC1 register to "0" (data in the UiTB register) - Apply a low-level ("L") signal to the $\overline{\text{CTS}}_i$ pin when the $\overline{\text{CTS}}$ function is selected
Receive Start Condition	To start receiving, the following requirements must be met ⁽²⁾ : <ul style="list-style-type: none"> - Set the RE bit in the UiC1 register to "1" (receive enabled) - Set the TE bit to "1" (transmit enabled) - Set the TI bit to "0" (data in the UiTB register)
Interrupt Request Generation Timing	<ul style="list-style-type: none"> • While transmitting, the following conditions can be selected: <ul style="list-style-type: none"> - The UiIRS bit in the UiC1 register is set to "0" (no data in the transmit buffer): when data is transferred from the UiTB register to the UART_i transmit register (transfer started) - The UiIRS bit is set to "1" (transmission completed): when a data transfer from the UART_i transmit register is completed • While receiving When data is transferred from the UART_i receive register to the UiRB register (reception completed)
Error Detect	Overrun error ⁽³⁾ This error occurs when the seventh bit of the next received data is read before reading the UiRB register
Selectable Function	<ul style="list-style-type: none"> • CLK polarity Selectable from the rising edge or falling edge of the transfer clock at transferred data output or input timing • LSB first or MSB first Selectable from data transmission or reception in either bit 0 or in bit 7 • Continuous receive mode Data can be received simultaneously by reading the UiRB register • Serial data logic inverse This function inverses transmitted/received data logically

NOTES:

1. The CNT3 to CNT0 bits in the TCSPR register select no division (n=0) or divide-by-2ⁿ (n=1 to 15).
2. To start transmission/reception when selecting the external clock, these conditions must be met after the CKPOL bit in the UiC0 register is set to "0" (data is transmitted on the falling edge of the transfer clock and data is received on the rising edge) and the CLK_i pin is held "H", or when the CKPOL bit is set to "1" (data is transmitted on the rising edge of the transfer clock and data is received on the falling edge) and the CLK_i pin is held "L".
3. If an overrun error occurs, the UiRB register is indeterminate. The IR bit setting in the SiRIC register does not change to "1" (interrupt requested).

Table 16.2 Register Settings in Clock Synchronous Serial I/O Mode

Register	Bit	Function
UiTB	7 to 0	Set transmit data
UiRB	7 to 0	Received data can be read
	OER	Overrun error flag
UiBRG	7 to 0	Set bit rate
UiMR	SMD2 to SMD0	Set to "0012"
	CKDIR	Select the internal clock or external clock
	IOPOL	Set to "0"
UiC0	CLK1, CLK0	Select count source for the UiBRG register
	CRS	Select $\overline{\text{CTS}}$ or $\overline{\text{RTS}}$ when using either
	TXEPT	Transmit register empty flag
	CRD	Enables or disables the CTS or RTS function
	NCH	Select output format of the TxDi pin
	CKPOL	Select transmit clock polarity
	UFORM	Select either LSB first or MSB first
UiC1	TE	Set to "1" to enable data transmission and reception
	TI	Transmit buffer empty flag
	RE	Set to "1" to enable data reception
	RI	Reception complete flag
	UiIRS	Select what causes the UARTi transmit interrupt to be generated
	UiRRM	Set to "1" when using continuous receive mode
	UiLCH	Set to "1" when using data logic inverse
	SCLKSTPB	Set to "0"
UiSMR	7 to 0	Set to "0016"
UiSMR2	7 to 0	Set to "0016"
UiSMR3	2 to 0	Set to "0002"
	NODC	Select clock output format
	7 to 4	Set to "00002"
UiSMR4	7 to 0	Set to "0016"

i=0 to 4

NOTE:

1. P70 and P71 are ports for the N-channel open drain output.

Table 16.5 Pin Settings (3)

Port	Function	Setting			
		PS3 Register ⁽¹⁾	PSL3 Register	PSC3 Register	PD9 Register ⁽¹⁾
P90	CLK3 input	PS3_0=0	-	-	PD9_0=0
	CLK3 output	PS3_0=1	-	-	-
P91	RxD3 input	PS3_1=0	-	-	PD9_1=0
P92	TxD3 output	PS3_2=1	PSL3_2=0	-	-
P93	CTS3 input	PS3_3=0	PSL3_3=0	-	PD9_3=0
	RTS3 output	PS3_3=1	-	-	-
P94	CTS4 input	PS3_4=0	PSL3_4=0	-	PD9_4=0
	RTS4 output	PS3_4=1	-	-	-
P95	CLK4 input	PS3_5=0	PSL3_5=0	-	PD9_5=0
	CLK4 output	PS3_5=1	-	-	-
P96	TxD4 output	PS3_6=1	-	PSC3_6=0	-
P97	RxD4 input	PS3_7=0	-	-	PD9_7=0

NOTE:

1. Set the PD9 and PS3 registers immediately after the PRC2 bit in the PRCR register is set to "1" (write enabled). Do not generate an interrupt or a DMA transfer between the instruction to set the PRC2 bit to "1" and the instruction to set the PD9 and PS3 registers.

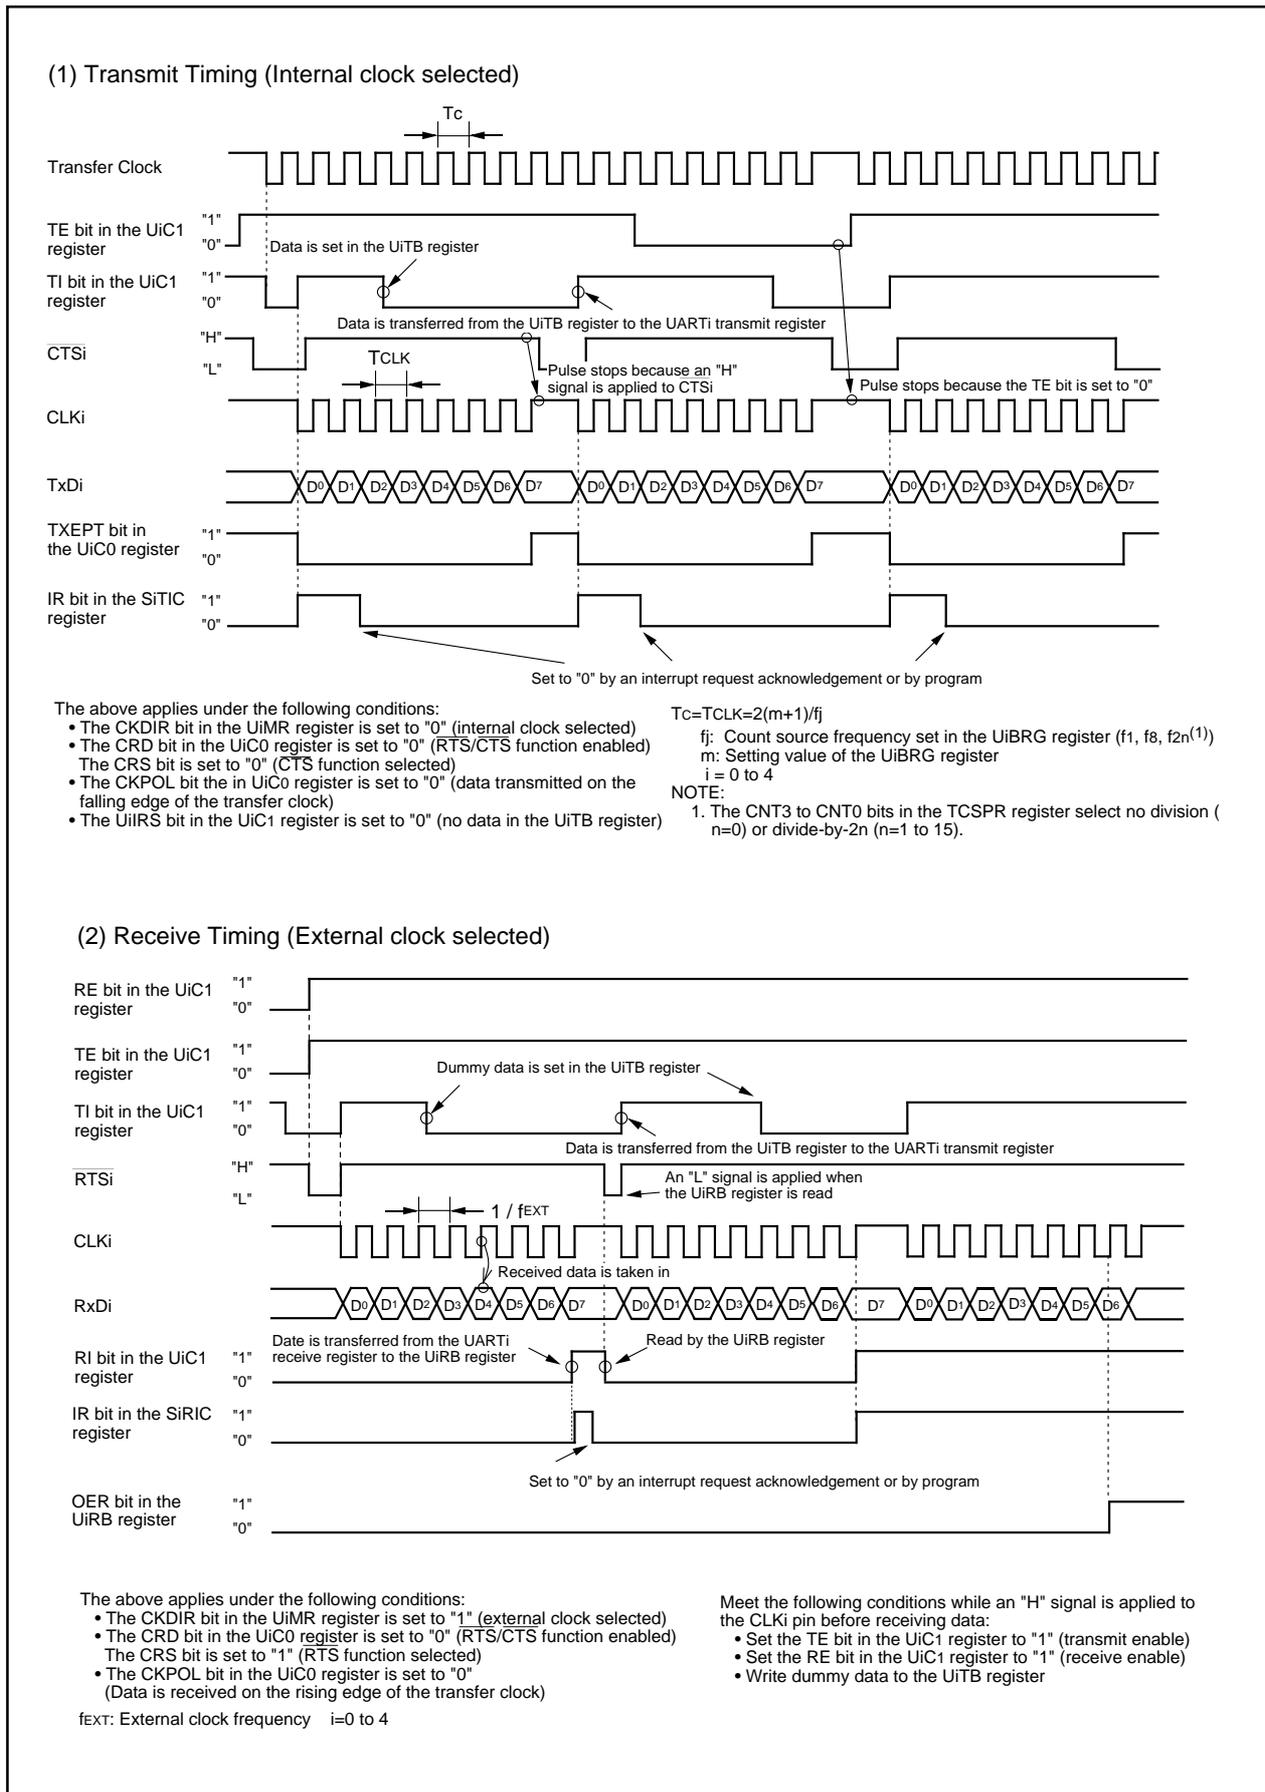

Figure 16.10 Transmit and Receive Operation

16.1.1 Selecting CLK Polarity Selecting

As shown in Figure 16.11, the CKPOL bit in the UiC0 register (i=0 to 4) determines the polarity of the transfer clock.

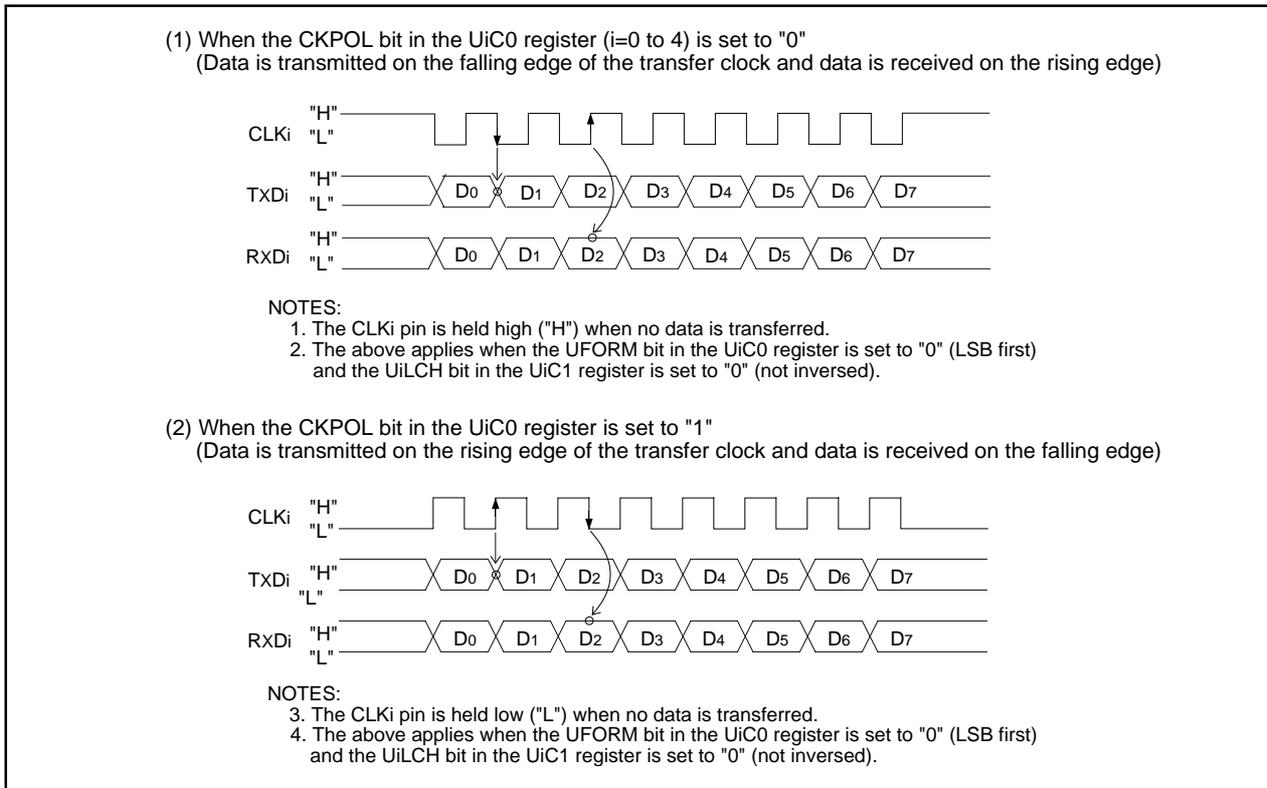

Figure 16.11 Transfer Clock Polarity

16.1.2 Selecting LSB First or MSB First

As shown in Figure 16.12, the UFORM bit in the UiC0 register (i=0 to 4) determines a data transfer format.

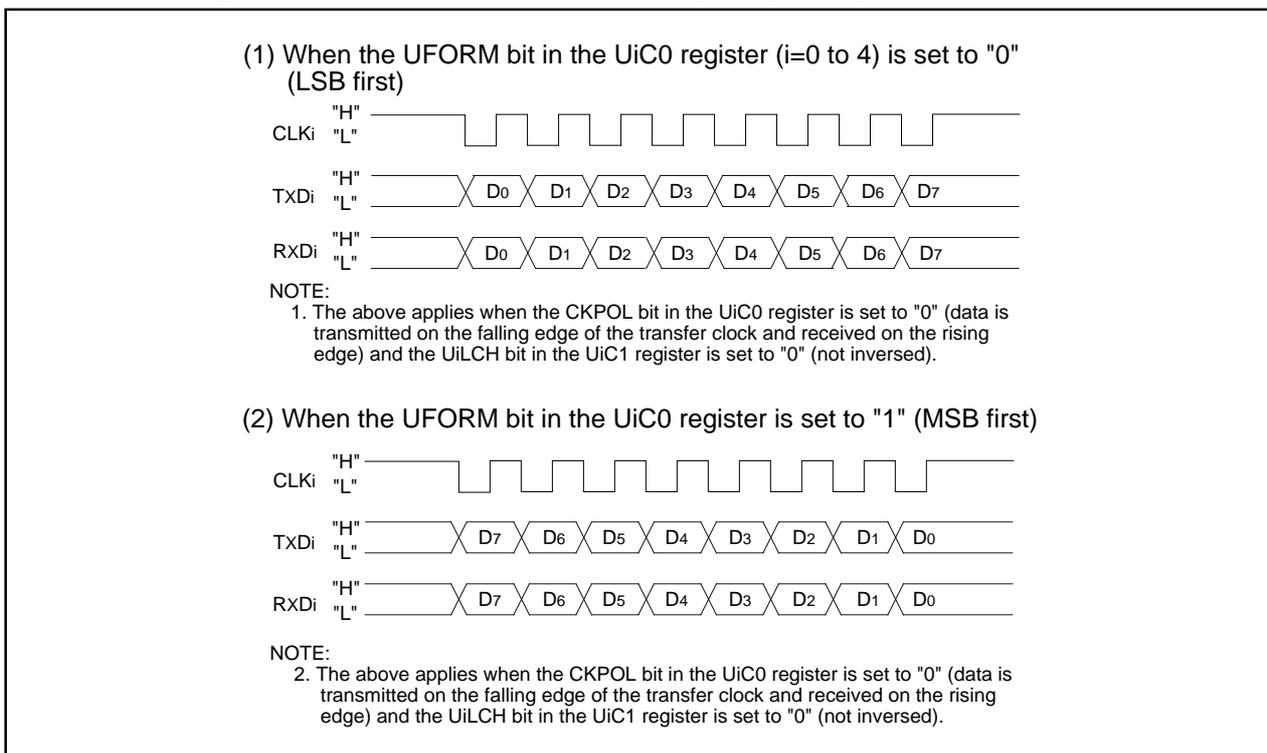

Figure 16.12 Transfer Format

16.1.3 Continuous Receive Mode

When the UiRRM bit in the UiC1 register (i=0 to 4) is set to "1" (continuous receive mode), the TI bit is set to "0" (data in the UiTB register) by reading the UiRB register. When the UiRRM bit is set to "1", do not set dummy data in the UiTB register by program.

16.1.4 Serial Data Logic Inverse

When the UiLCH bit (i=0 to 4) in the UiC1 register is set to "1" (inverse), data logic written in the UiTB register is inverted when transmitted. The inverted receive data logic can be read by reading the UiRB register. Figure 16.13 shows a switching example of the serial data logic.

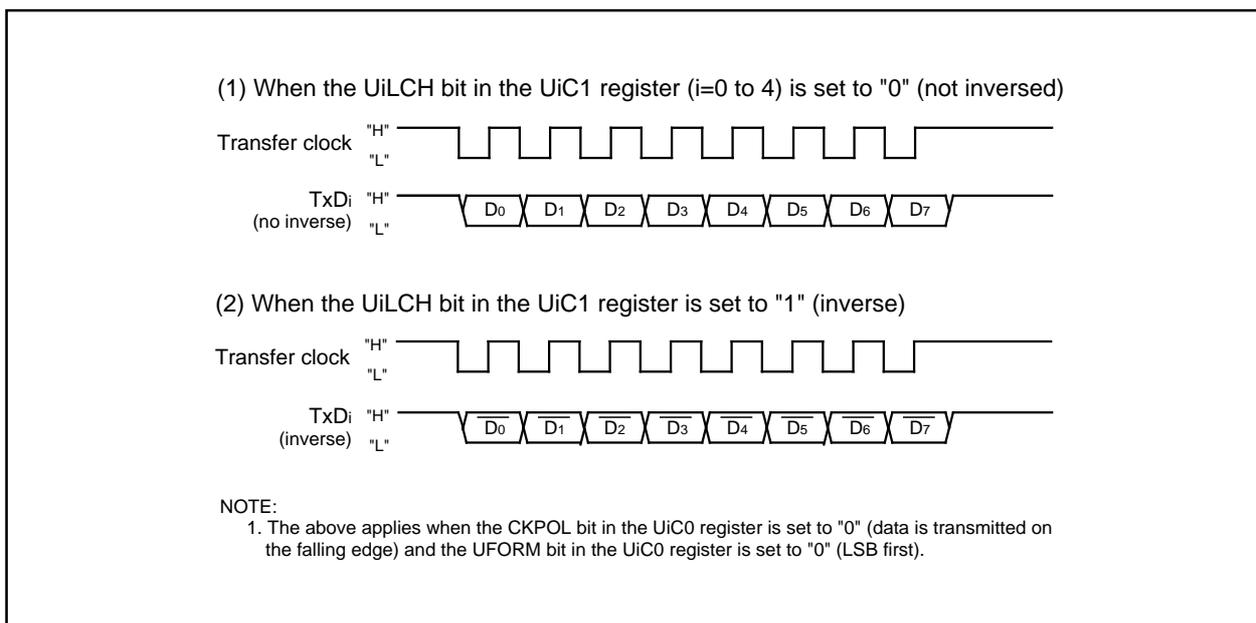

Figure 16.13 Serial Data Logic Inverse

16.2 Clock Asynchronous Serial I/O (UART) Mode

In UART mode, data is transmitted and received after setting a desired bit rate and data transfer format. Table 16.6 lists specifications of UART mode.

Table 16.6 UART Mode Specifications

Item	Specification
Transfer Data Format	<ul style="list-style-type: none"> • Character bit (transfer data) : selected from 7 bits, 8 bits, or 9 bits long • Start bit: 1 bit long • Parity bit: selected from odd, even, or none • Stop bit: selected from 1 bit or 2 bits long
Transfer Clock	<ul style="list-style-type: none"> • The CKDIR bit in the UiMR register is set to "0" (internal clock selected): $f_j/16(m+1)$ $f_j = f_1, f_8, f_{2n}^{(1)}$ m: setting value of the UiBRG register, 0016 to FF16 • The CKDIR bit is set to "1" (external clock selected): $f_{EXT}/16(m+1)$ f_{EXT}: clock applied to the CLKi pin
Transmit/Receive Control	Select from CTS function, RTS function or CTS/RTS function disabled
Transmit Start Condition	To start transmitting, the following requirements must be met: <ul style="list-style-type: none"> - Set the TE bit in the UiC1 register to "1" (transmit enabled) - Set the TI bit in the UiC1 register to "0" (data in the UiTB register) - Apply a low-level ("L") signal to the CTSi pin when the CTS function is selected
Receive Start Condition	To start receiving, the following requirements must be met: <ul style="list-style-type: none"> - Set the RE bit in the UiC1 register to "1" (receive enabled) - The start bit is detected
Interrupt Request Generation Timing	<p>While transmitting, the following condition can be selected:</p> <ul style="list-style-type: none"> - The UiIRS bit in the UiC1 register is set to "0" (no data in the UiTB register): when data is transferred from the UiTB register to the UARTi transmit register (transfer started) - The UiIRS bit is set to "1" (transmission completed): when data transmission from the UARTi transfer register is completed <p>While receiving</p> <ul style="list-style-type: none"> - when data is transferred from the UARTi receive register to the UiRB register (reception completed)
Error Detect	<ul style="list-style-type: none"> • Overrun error⁽²⁾ This error occurs when the bit before the last stop bit of the next received data is read prior to reading the UiRB register (the first stop bit when selecting 2 stop bits) • Framing error This error occurs when the number of stop bits set is not detected • Parity error When parity is enabled, this error occurs when the number of "1" in parity and character bits does not match the number of "1" set • Error sum flag This flag is set to "1" when any of an overrun, framing or parity errors occur
Selectable Function	<ul style="list-style-type: none"> • LSB first or MSB first Selectable from data transmission or reception in either bit 0 or in bit 7 • Serial data logic inverse Logic values of data to be transmitted and received data are inversed. The start bit and stop bit are not inversed • TxD and RxD I/O polarity Inverse TxD pin output and RxD pin input are inversed. All I/O data levels are also inversed

NOTES:

1. The CNT3 to CNT0 bits in the TCSPR register select no division (n=0) or divide-by-2n (n=1 to 15).
2. If an overrun error occurs, the UiRB register is indeterminate. The IR bit setting in the SiRIC register does not change to "1" (interrupt requested).

Table 16.7 lists register settings. Tables 16.8 to 16.10 list pin settings. When UART_i (i=0 to 4) operating mode is selected, the TxD_i pin outputs a high-level ("H") signal before transfer is started (the TxD_i pin is in a high-impedance state when the N-channel open drain output is selected). Figure 16.14 shows an example of a transmit operation in UART mode. Figure 16.15 shows an example of a receive operation in UART mode.

Table 16.7 Register Settings in UART Mode

Register	Bit	Function
UiTB	8 to 0	Set transmit data ⁽¹⁾
UiRB	8 to 0	Received data can be read ⁽¹⁾
	OER, FER, PER, SUM	Error flags
UiBRG	7 to 0	Set bit rate
UiMR	SMD2 to SMD0	Set to "1002" when transfer data is 7 bits long Set to "1012" when transfer data is 8 bits long Set to "1102" when transfer data is 9 bits long
	CKDIR	Select the internal clock or external clock
	STPS	Select stop bit length
	PRY, PRYE	Select parity enabled or disabled, odd or even
	IOPOL	Select TxD and RxD I/O polarity
UiC0	CLK1, CLK0	Select count source for the UiBRG register
	CRS	Select either $\overline{\text{CTS}}$ or $\overline{\text{RTS}}$ when using either
	TXEPT	Transfer register empty flag
	CRD	Select the $\overline{\text{CTS}}$ or $\overline{\text{RTS}}$ function enabled or disabled
	NCH	Select output format of the TxD _i pin
	CKPOL	Set to "0"
	UFORM	Select the LSB first or MSB first when a transfer data is 8 bits long Set to "0" when transfer data is 7 bits or 9 bits long
UiC1	TE	Set to "1" to enable data transmission
	TI	Transfer buffer empty flag
	RE	Set to "1" to enable data reception
	RI	Reception complete flag
	UiIRS	Select what causes the UART _i transmit interrupt to be generated
	UiRRM	Set to "0"
	UiLCH	Select whether data logic is inversed or not inversed when a transfer data is 7 bits or 8 bits long. Set to "0" when transfer data is 9 bits long
	UiERE	Set to either "0" or "1"
UiSMR	7 to 0	Set to "0016"
UiSMR2	7 to 0	Set to "0016"
UiSMR3	7 to 0	Set to "0016"
UiSMR4	7 to 0	Set to "0016"

NOTE:

1. Use bits 0 to 6 when transfer data is 7 bits long, bits 0 to 7 when 8 bits long, bits 0 to 8 when 9 bits long.

Table 16.8 Pin Settings in UART Mode (1)

Port	Function	Setting		
		PS0 Register	PSL0 Register	PD6 Register
P60	CTS0 input	PS0_0=0	–	PD6_0=0
	RTS0 output	PS0_0=1	–	–
P61	CLK0 input	PS0_1=0	–	PD6_1=0
P62	RxD0 input	PS0_2=0	–	PD6_2=0
P63	TxD0 output	PS0_3=1	–	–
P64	CTS1 input	PS0_4=0	–	PD6_4=0
	RTS1 output	PS0_4=1	PSL0_4=0	–
P65	CLK1 input	PS0_5=0	–	PD6_5=0
P66	RxD1 input	PS0_6=0	–	PD6_6=0
P67	TxD1 output	PS0_7=1	–	–

		PS1 Register	PSL1 Register	PSC Register	PD7 Register
P70 ⁽¹⁾	TxD2 output	PS1_0=1	PSL1_0=0	PSC_0=0	–
P71 ⁽¹⁾	RxD2 input	PS1_1=0	–	–	PD7_1=0
P72	CLK2 input	PS1_2=0	–	–	PD7_2=0
P73	CTS2 input	PS1_3=0	–	–	PD7_3=0
	RTS2 output	PS1_3=1	PSL1_3=0	PSC_3=0	–

NOTE:

1. P70 and P71 are ports for the N-channel open drain output.

Table 16.10 Pin Settings (3)

Port	Function	Setting			
		PS3 Register ⁽¹⁾	PSL3 Register	PSC3 Register	PD9 Register ⁽¹⁾
P90	CLK3 input	PS3_0=0	–	–	PD9_0=0
P91	RxD3 input	PS3_1=0	–	–	PD9_1=0
P92	TxD3 output	PS3_2=1	PSL3_2=0	–	–
P93	CTS3 input	PS3_3=0	PSL3_3=0	–	PD9_3=0
	RTS3 output	PS3_3=1	–	–	–
P94	CTS4 input	PS3_4=0	PSL3_4=0	–	PD9_4=0
	RTS4 output	PS3_4=1	–	–	–
P95	CLK4 input	PS3_5=0	PSL3_5=0	–	PD9_5=0
P96	TxD4 output	PS3_6=1	–	PSC3_6=0	–
P97	RxD4 input	PS3_7=0	–	–	PD9_7=0

NOTE:

1. Set the PD9 and PS3 registers set immediately after the PRC2 bit in the PRCR register is set to "1" (write enabled). Do not generate an interrupt or a DMA transfer between the instruction to set to the PRC2 bit to "1" and the instruction to set the PD9 and PS3 registers.

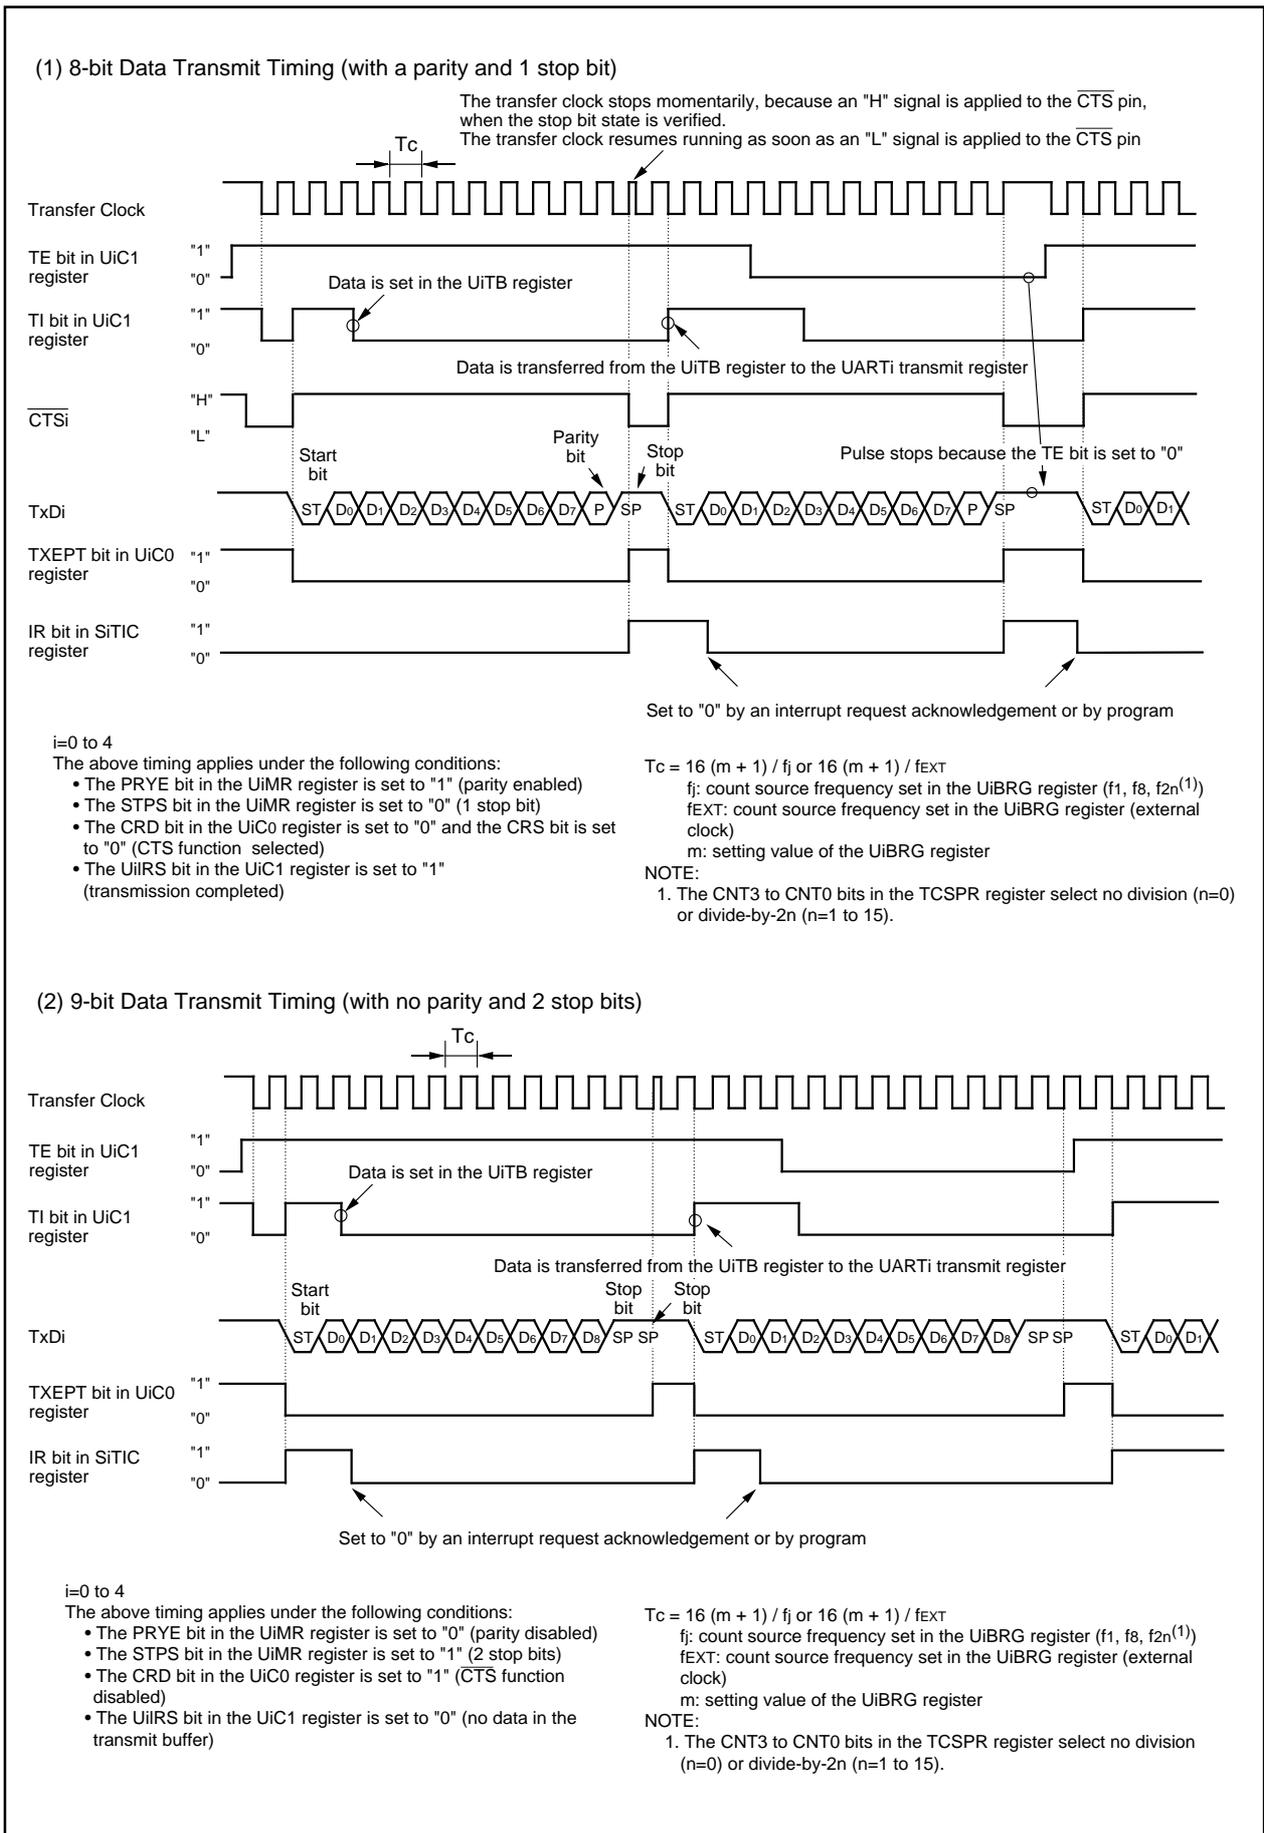

Figure 16.14 Transmit Operation

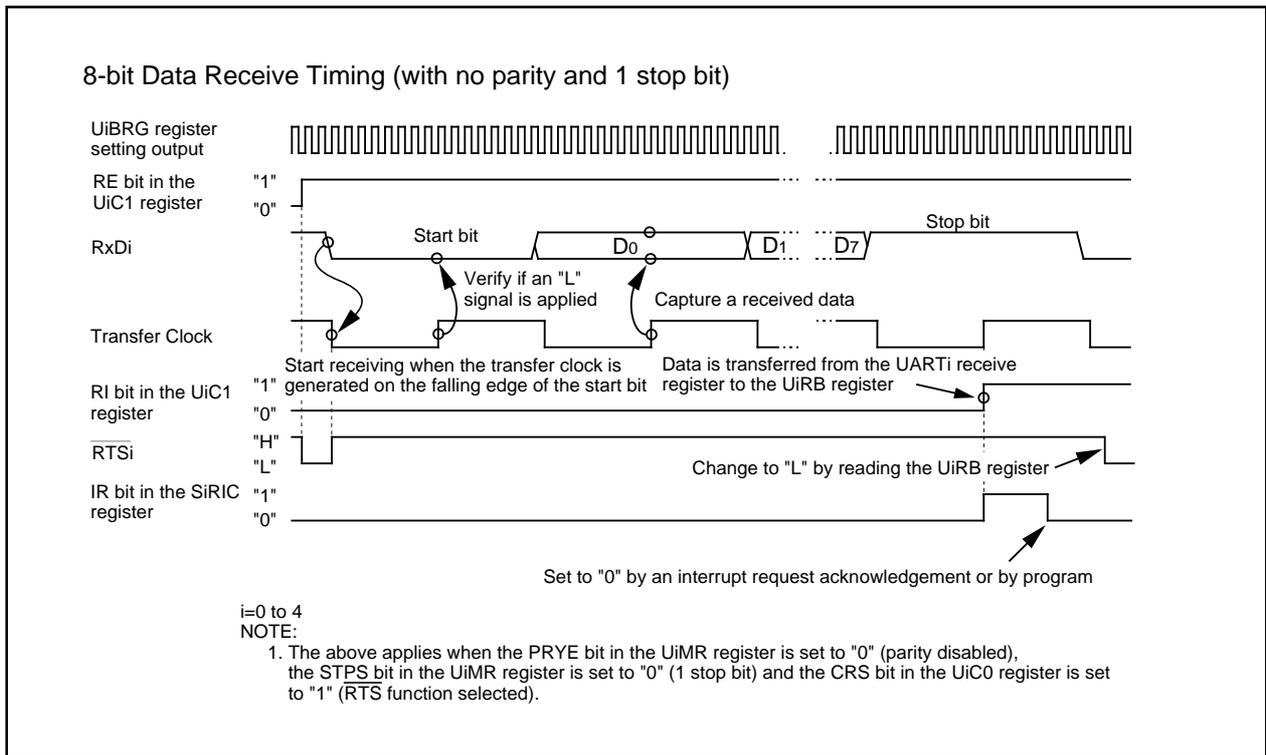

Figure 16.15 Receive Operation

16.2.1 Bit Rate

In UART mode, bit rate is clock frequency which is divided by a setting value of the UiBRG ($i=0$ to 4) register and again divided by 16. Table 16.11 lists an example of bit rate setting.

Table 16.11 Bit Rate

Bit Rate (bps)	Count Source of UiBRG	Peripheral Function Clock: 16MHz		Peripheral Function Clock: 24MHz		Peripheral Function Clock: 32MHz	
		Setting Value of UiBRG: n	Actual Bit Rate (bps)	Setting Value of UiBRG: n	Actual Bit Rate (bps)	Setting Value of UiBRG: n	Actual Bit Rate (bps)
1200	f8	103 (67h)	1202	155 (96h)	1202	207 (CFh)	1202
2400	f8	51 (33h)	2404	77 (46h)	2404	103 (67h)	2404
4800	f8	25 (19h)	4808	38 (26h)	4808	51 (33h)	4808
9600	f1	103 (67h)	9615	155 (96h)	9615	207 (CFh)	9615
14400	f1	68 (44h)	14493	103 (67h)	14423	138 (8Ah)	14388
19200	f1	51 (33h)	19231	77 (46h)	19231	103 (67h)	19231
28800	f1	34 (22h)	28571	51 (33h)	28846	68 (44h)	28986
31250	f1	31 (1Fh)	31250	47 (2Fh)	31250	63 (3Fh)	31250
38400	f1	25 (19h)	38462	38 (26h)	38462	51 (33h)	38462
51200	f1	19 (13h)	50000	28 (1Ch)	51724	38 (26h)	51282

16.2.2 Selecting LSB First or MSB First

As shown in Figure 16.16, the UFORM bit in the UiC0 register (i=0 to 4) determines data transfer format. This function is available for 8-bit transfer data.

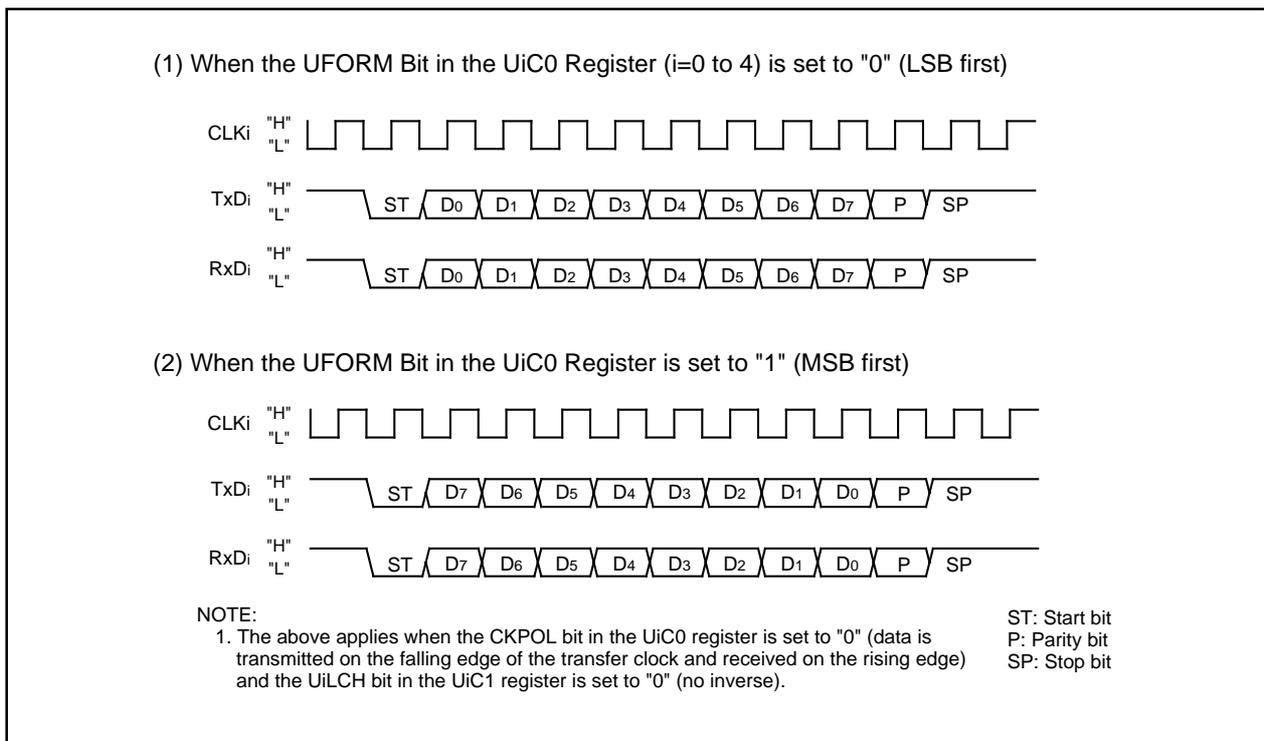

Figure 16.16 Transfer Format

16.2.3 Serial Data Logic Inverse

When the UiLCH bit (i=0 to 4) in the UiC1 register is set to "1" (inverse), data logic written in the UiTB register is inverted when transmitted. The inverted receive data logic can be read by reading the UiRB register. Figure 16.17 shows a switching example of the serial data logic.

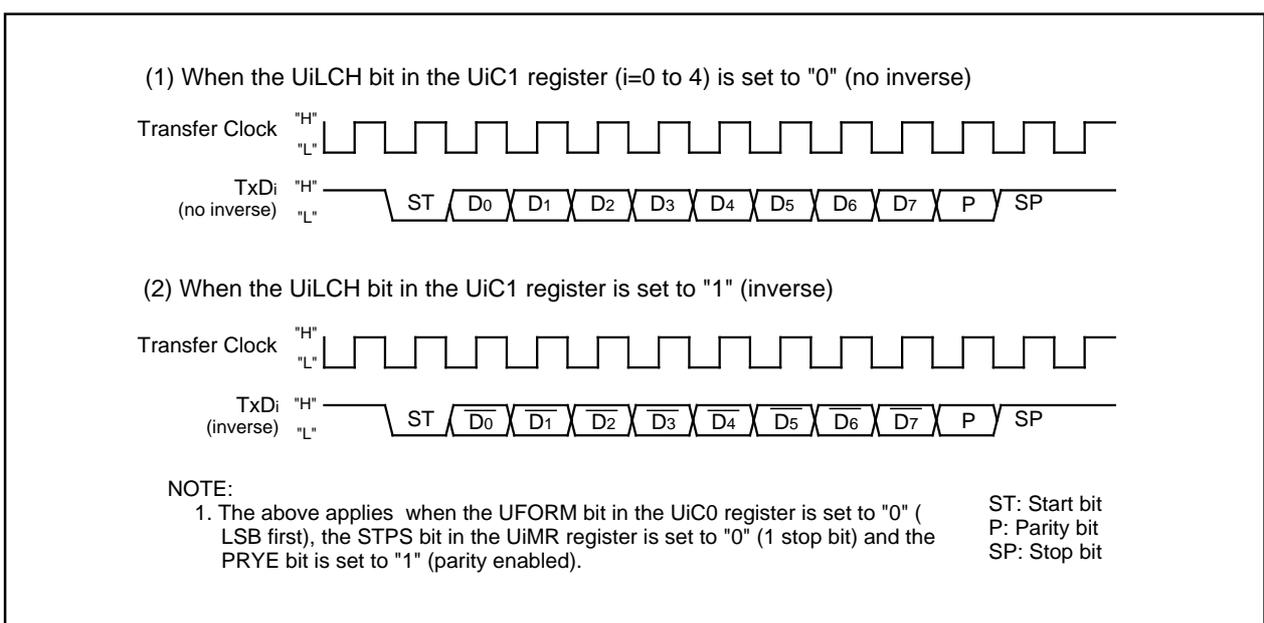

Figure 16.17 Serial Data Logic Inverse

16.2.4 TxD and RxD I/O Polarity Inverse

TxD pin output and RxD pin input are inverted. All I/O data level, including the start bit, stop bit and parity bit, are inverted. Figure 16.18 shows TxD and RxD I/O polarity inverse.

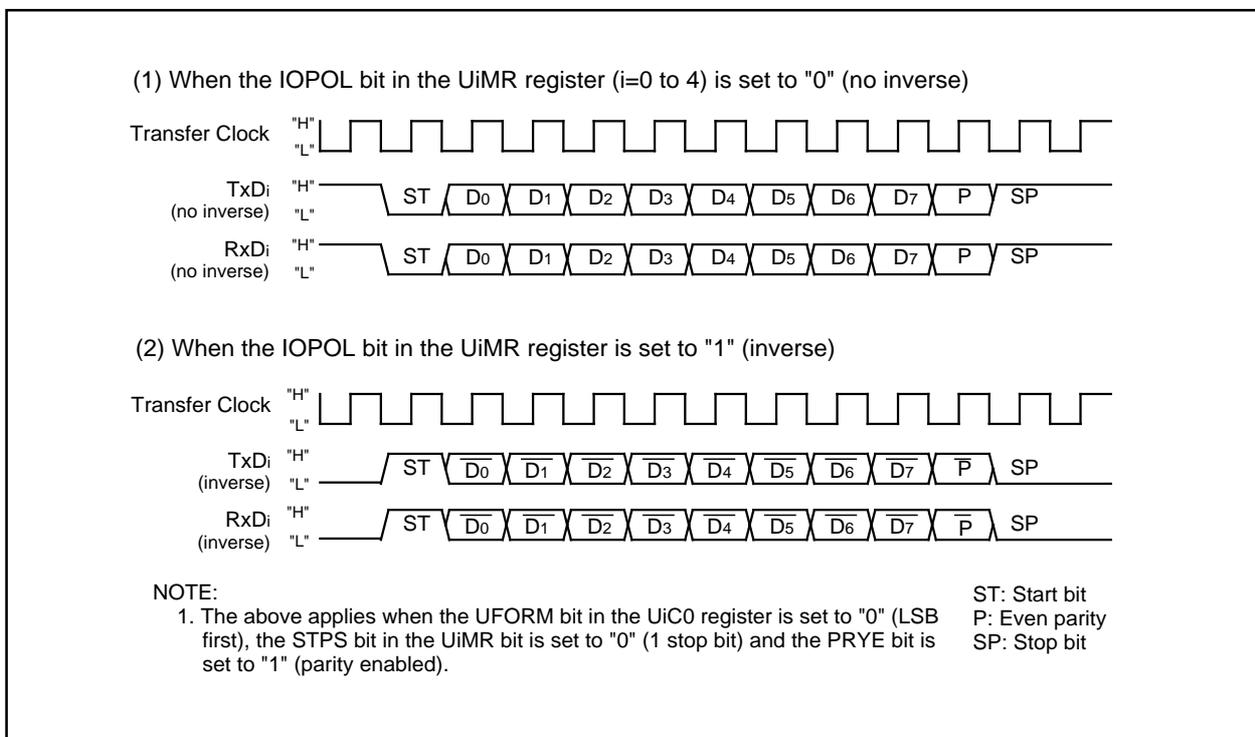

Figure 16.18 TxD and RxD I/O Polarity Inverse

16.3 Special Mode 1 (I²C Mode)

I²C mode is a mode to communicate with external devices with a simplified I²C. Table 16.12 lists specifications of I²C mode. Table 16.13 lists register settings, Table 16.14 lists each function. Figure 16.19 shows a block diagram of I²C mode. Figure 16.20 shows timings for transfer to the UiRB register (i=0 to 4) and interrupts. Tables 16.15 to 16.17 list pin settings.

As shown in Table 16.12, I²C mode is entered when the SMD2 to SMD0 bits in the UiMR register is set to "0102" and the IICM bit in the UiSMR register is set to "1". Output signal from the SDAi pin changes after the SCLi pin level becomes low ("L") and stabilizes due to a SDAi transmit output via the delay circuit.

Table 16.12 I²C Mode Specifications

Item	Specifications
Interrupt	Start condition detect, stop condition detect, no acknowledgment detect, acknowledgment detect
Selectable Function	<ul style="list-style-type: none"> • Arbitration lost Selectable from update timing of the ABT bit in the UiRB register. Refer to 16.3.3 Arbitration • SDAi digital delay Selectable from no digital delay or 2 to 8 cycle delay of the count source of of the UiBRG register. Refer to 16.3.5 SDA Output • Clock phase setting Selectable from clock delay or no clock delay. Refer to 16.3.4 Transfer Clock

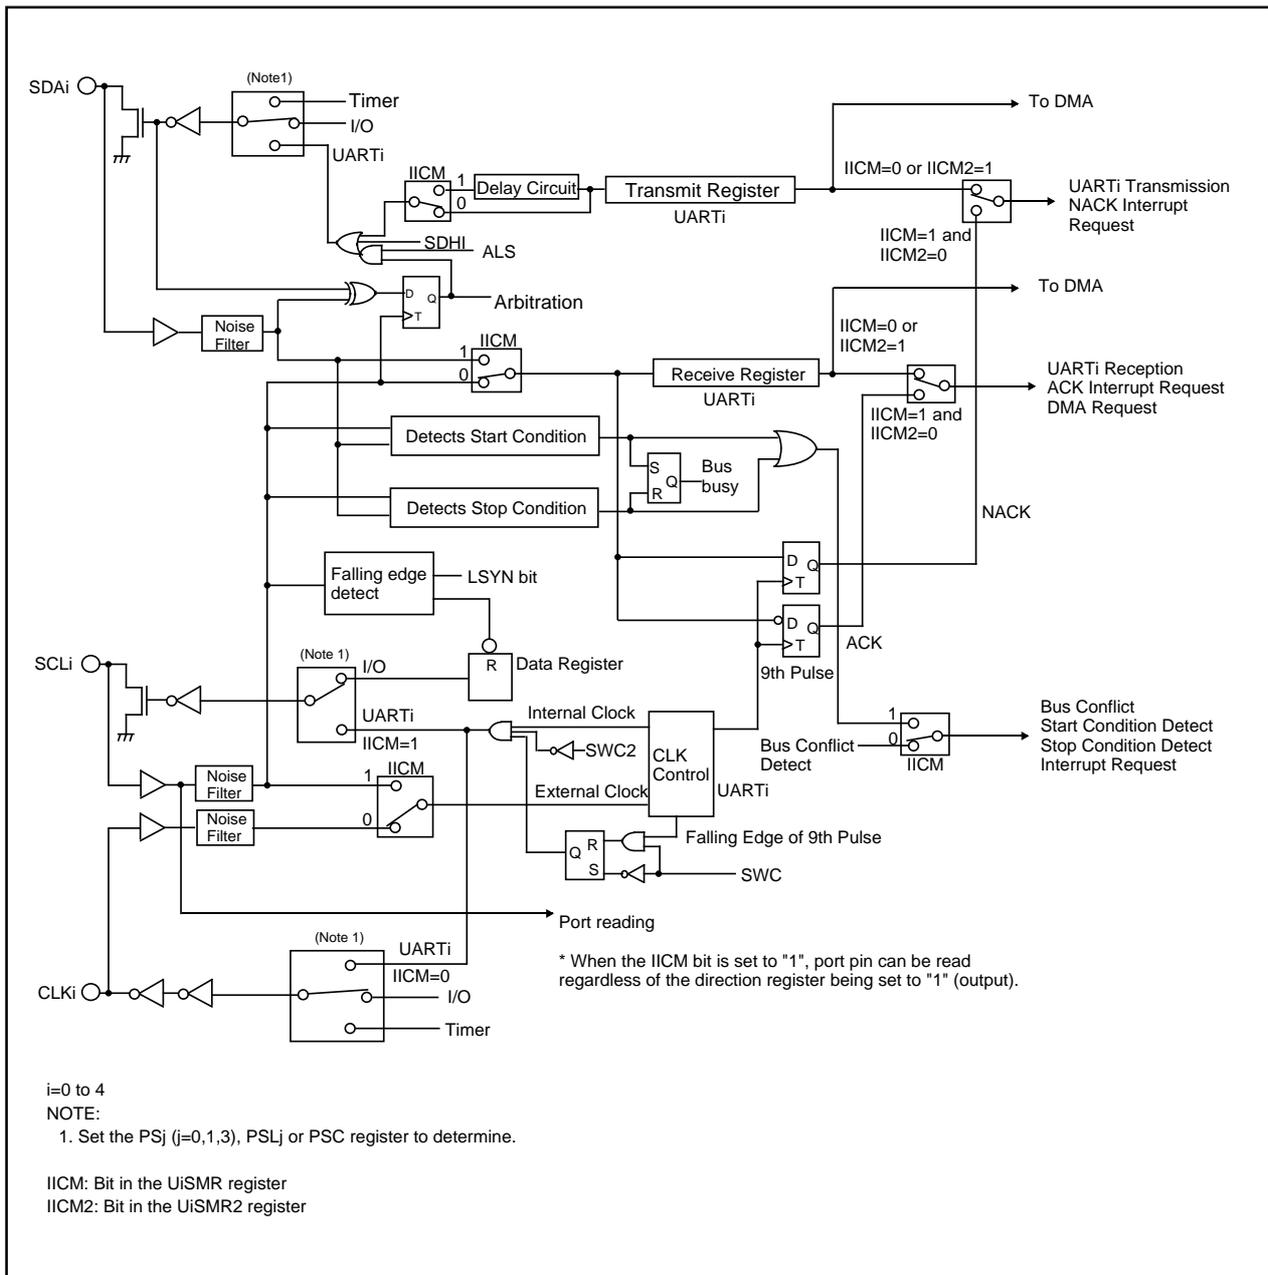

Figure 16.19 I²C Mode Block Diagram

Table 16.13 Register Settings in I²C Mode

Register	Bit	Function	
		Master	Slave
UiTB	7 to 0	Set transmit data	
UiRB	7 to 0	Received data can be read	
	8	ACK or NACK bit can be read	
	ABT	Arbitration lost detect flag	Disabled
	OER	Overrun error flag	
UiBRG	7 to 0	Set bit rate	Disabled
UiMR	SMD2 to SMD0	Set to "0102"	
	CKDIR	Set to "0"	Set to "1"
	IOPOL	Set to "0"	
UiC0	CLK1, CLK0	Select count source of the UiBRG register	Disabled
	CRS	Disabled because the CRD bit is set to "1"	
	TXEPT	Transfer register empty flag	
	CRD, NCH	Set to "1"	
	CKPOL	Set to "0"	
	UFORM	Set to "1"	
UiC1	TE	Set to "1" to enable data transmission	
	TI	Transfer buffer empty flag	
	RE	Set to "1" to enable data reception	
	RI	Reception complete flag	
	UiRRM, UiLCH, UIERE	Set to "0"	
UiSMR	IICM	Set to "1"	
	ABC	Select an arbitration lost detect timing	Disabled
	BBS	Bus busy flag	
	7 to 3	Set to "000002"	
UiSMR2	IICM2	See Table 16.14	
	CSC	Set to "1" to enable clock synchronization	Set to "0"
	SWC	Set to "1" to fix an "L" signal output from SCLi on the falling edge of the ninth bit of the transfer clock	
	ALS	Set to "1" to terminate SDAi output when detecting the arbitration lost	Not used. Set to "0"
	STC	Not used. Set to "0"	Set to "1" to reset UARTi by detecting the start condition
	SWC2	Set to "1" for an "L" signal output from SCL forcibly	
	SDHI	Set to "1" to disable SDA output	
	SU1HIM	Set to "0"	
	UiSMR3	SSE	Set to "0"
CKPH		See Table 16.14	
DINC, NODC, ERR		Set to "0"	
DL2 to DL0		Set digital delay value for SDAi	
UiSMR4	STAREQ	Set to "1" when generating a start condition	Not used. Set to "0"
	RSTAREQ	Set to "1" when generating a restart condition	
	STPREQ	Set to "1" when generating a stop condition	
	STSPSEL	Set to "1" when using a condition generating function	
	ACKD	Select ACK or NACK	
	ACKC	Set to "1" for ACK data output	
	SCLHI	Set to "1" to enable SCL output stop when detecting stop condition	Not used. Set to "0"
	SWC9	Not used. Set to "0"	Set to "1" to fix an "L" signal output from SCLi on the falling edge of the ninth bit of the transfer clock
IFSR	IFSR6, IFSR7	Set to "1"	

i=0 to 4

Table 16.14 I²C Mode Functions

Function	Clock Synchronous Serial I/O Mode (SMD2 to SMD0=0012, IICM=0)	I ² C Mode (SMD2 to SMD0=0102, IICM=1)			
		IICM2=0 (NACK/ACK interrupt)		IICM2=1 (UART transmit / UART receive interrupt)	
		CKPH=0 (No clock delay)	CKPH=1 (Clock delay)	CKPH=0 (No clock delay)	CKPH=1 (Clock delay)
Source for Interrupt Numbers 39 to 41 ⁽¹⁾ (See Figure 16.20)	-	Start condition or stop condition detect (See Table 16.18)			
Source for Interrupt Number 17, 19, 33, 35 and 37 ⁽¹⁾ (See Figure 16.20)	UARTi Transmission - Transmission started or completed (selected by the UiIRS register)	No Acknowledgement Detection (NACK) - Rising edge of 9th bit of SCLi	UARTi Transmission - Rising edge of 9th bit of SCLi	UARTi Transmission - Next falling edge after the 9th bit of SCLi	
Source for Interrupt Numbers 18, 20, 34, 36 and 38 ⁽¹⁾ (See Figure 16.20)	UARTi Reception - Receiving at 8th bit CKPOL=0(rising edge) CKPOL=1(falling edge)	Acknowledgement Detection (ACK) - Rising edge of 9th bit of SCLi	UARTi Reception - Falling edge of 9th bit of SCLi		
Data Transfer Timing from the UART Receive Shift Register to the UiRB Register	CKPOL=0(rising edge) CKPOL=1(falling edge)	Rising edge of 9th bit of SCLi	Falling edge of 9th bit of SCLi	Falling edge and rising edge of 9th bit of SCLi	
UARTi Transmit Output Delay	No delay	Delay			
P63, P67, P70, P92, P96 Pin Functions	TxDi output	SDAi input and output			
P62, P66, P71, P91, P97 Pin Functions	RxDi input	SCLi input and output			
P61, P65, P72, P90, P95 Pin Functions	Select CLKi input or output	- (Not used in I ² C mode)			
Noise Filter Width	15 ns	200 ns			
Reading RxDi and SCLi Pin Levels	Can be read if port direction bit is set to "0"	Can be read regardless of the port direction bit			
Default Value of TxDi, SDAi Output	CKPOL=0 (H) CKPOL=1 (L)	Values set in the port register before entering I ² C mode ⁽²⁾			
SCLi Default and End Value	-	H	L	H	L
Source for DMA (See Figure 16.20)	UARTi reception	Acknowledgement detection (ACK)	UARTi Reception - Falling edge of 9th bit of SCLi		
Store Received Data	1st to 8th bits of the received data are stored into bits 7 to 0 in the UiRB register	1st to 8th bits of the received data are stored into bits 7 to 0 in the UiRB register	1st to 7th bits of the received data are stored into bits 6 to 0 in the UiRB register. 8th bit is stored into bit 8 in the UiRB register.		
			1st to 8th bits are stored into bits 7 to 0 in the UiRB register ⁽³⁾		
Reading Received Data	The UiRB register status is read	Bits 6 to 0 in the UiRB registers ⁽⁴⁾ are read as bit 7 to 1. Bit 8 in the UiRB register is read as bit 0			

i=0 to 4

NOTES:

- Use the following procedure to change what causes an interrupt to be generated.
 - Disable interrupt of corresponding interrupt number.
 - Change what causes an interrupt to be generated.
 - Set the IR bit of a corresponding interrupt number to "0" (no interrupt requested).
 - Set the ILVL2 to ILVL0 bits of a corresponding interrupt number.
- Set default value of the SDAi output when the SMD2 to SMD0 bits in the UiMR register are set to "0002" (serial I/O disabled).
- Second data transfer to the UiRB register (on the rising edge of the ninth bit of SCLi).
- First data transfer to the UiRB register (on the falling edge of the ninth bit of SCLi).

	SDA0 input	PS0_3=0	-	PD6_3=0
P66	SCL1 output	PS0_6=1	PSL0_6=0	-
	SCL1 input	PS0_6=0	-	PD6_6=0
P67	SDA1 output	PS0_7=1	-	-
	SDA1 input	PS0_7=0	-	PD6_7=0

Table 16.16 Pin Settings (2)

Port	Function	Setting			
		PS1 Register	PSL1 Register	PSC Register	PD7 Register
P70 ⁽¹⁾	SDA2 output	PS1_0=1	PSL1_0=0	PSC_0=0	-
	SDA2 input	PS1_0=0	-	-	PD7_0=0
P71 ⁽¹⁾	SCL2 output	PS1_1=1	PSL1_1=1	PSC_1=0	-
	SCL2 input	PS1_1=0	-	-	PD7_1=0

NOTE:

1. P70 and P71 are ports for the N-channel open drain output.

Table 16.17 Pin Settings (3)

Port	Function	Setting			
		PS3 Register ⁽¹⁾	PSL3 Register	PSC3 Register	PD9 Register ⁽¹⁾
P91	SCL3 output	PS3_1=1	PSL3_1=0	-	-
	SCL3 input	PS3_1=0	-	-	PD9_1=0
P92	SDA3 output	PS3_2=1	PSL3_2=0	-	-
	SDA3 input	PS3_2=0	-	-	PD9_2=0
P96	SDA4 output	PS3_6=1	-	PSC3_6=0	-
	SDA4 input	PS3_6=0	-	-	PD9_6=0
P97	SCL4 output	PS3_7=1	PSL3_7=0	-	-
	SCL4 input	PS3_7=0	-	-	PD9_7=0

NOTE:

1. Set the PD9 and PS3 registers immediately after the PRC2 bit in the PRCR register is set to "1" (write enabled). Do not generate an interrupt or a DMA transfer between the instruction to set the PRC2 bit to "1" and the instruction to set the PD9 and PS3 registers.

16.3.1 Detecting Start Condition and Stop Condition

The microcomputer detects either a start condition or stop condition. The start condition detect interrupt is generated when the SCL_i (i=0 to 4) pin level is held high ("H") and the SDA_i pin level changes "H" to low ("L"). The stop condition detect interrupt is generated when the SCL_i pin level is held "H" and the SDA_i pin level changes "L" to "H". The start condition detect interrupt shares interrupt control registers and vectors with the stop condition detect interrupt. The BBS bit in the UiSMR register determines which interrupt is requested.

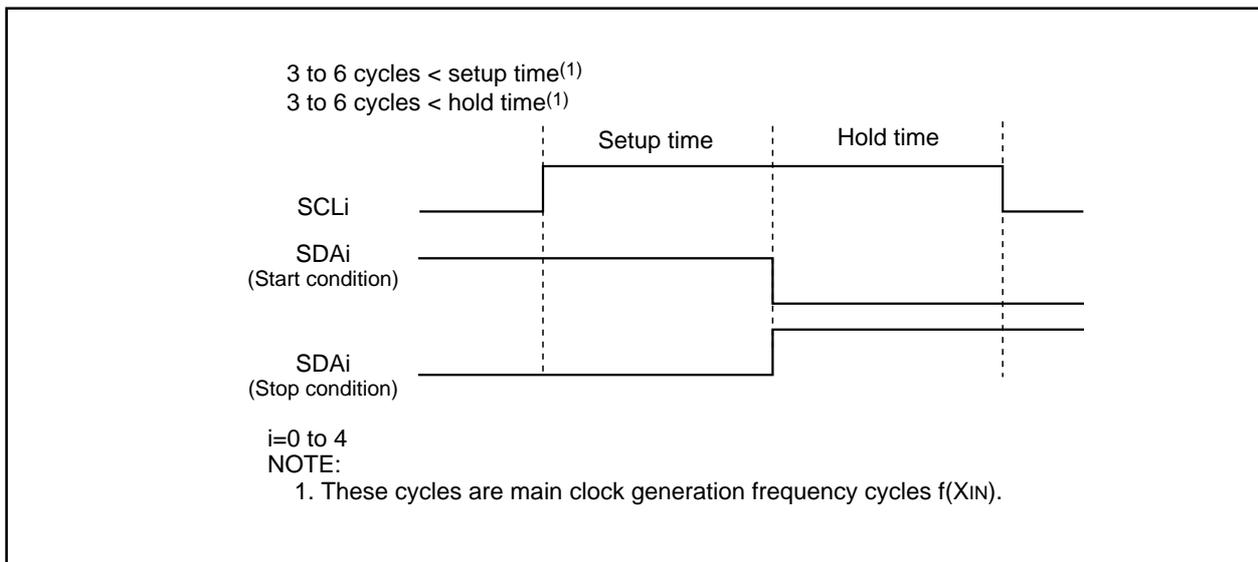

Figure 16.21 Start Condition or Stop Condition Detecting

16.3.2 Start Condition or Stop Condition Output

The start condition is generated when the STAREQ bit in the UiSMR4 register (i=0 to 4) is set to "1" (start). The restart condition is generated when the RSTAREQ bit in the UiSMR4 register is set to "1" (start). The stop condition is generated the STPREQ bit in the UiSMR4 is set to "1" (start).

The start condition is output when the STAREQ bit is set to "1" and the STSPSEL bit in the UiSMR4 register is set to "1" (start or stop condition generating circuit selected). The restart condition output is provided when the RSTAREQ bit and STSPSEL bit are set to "1". The stop condition output is provided when the STPREQ bit and the STSPSEL bit are set to "1".

When the start condition, stop condition or restart condition is output, do not generate an interrupt between the instruction to set the STAREQ bit, STPREQ bit or RSTAREQ bit to "1" and the instruction to set the STSPSEL bit to "1". When the start condition is output, set the STAREQ bit to "1" before the STSPSEL bit is set to "1".

Table 16.18 lists function of the STSPSEL bit. Figure 16.22 shows functions of the STSPSEL bit.

Table 16.18 STSPSEL Bit Function

Function	STSPSEL = 0	STSPSEL = 1
Start condition and stop condition output	Program with ports determines how the start condition or stop condition output is provided	The STAREQ bit, RSTAREQ bit and STPREQ bit determine how the start condition or stop condition output is provided
Timing to generate start condition and stop condition interrupt requests	The start condition and stop condition are detected	Start condition and stop condition generation are completed

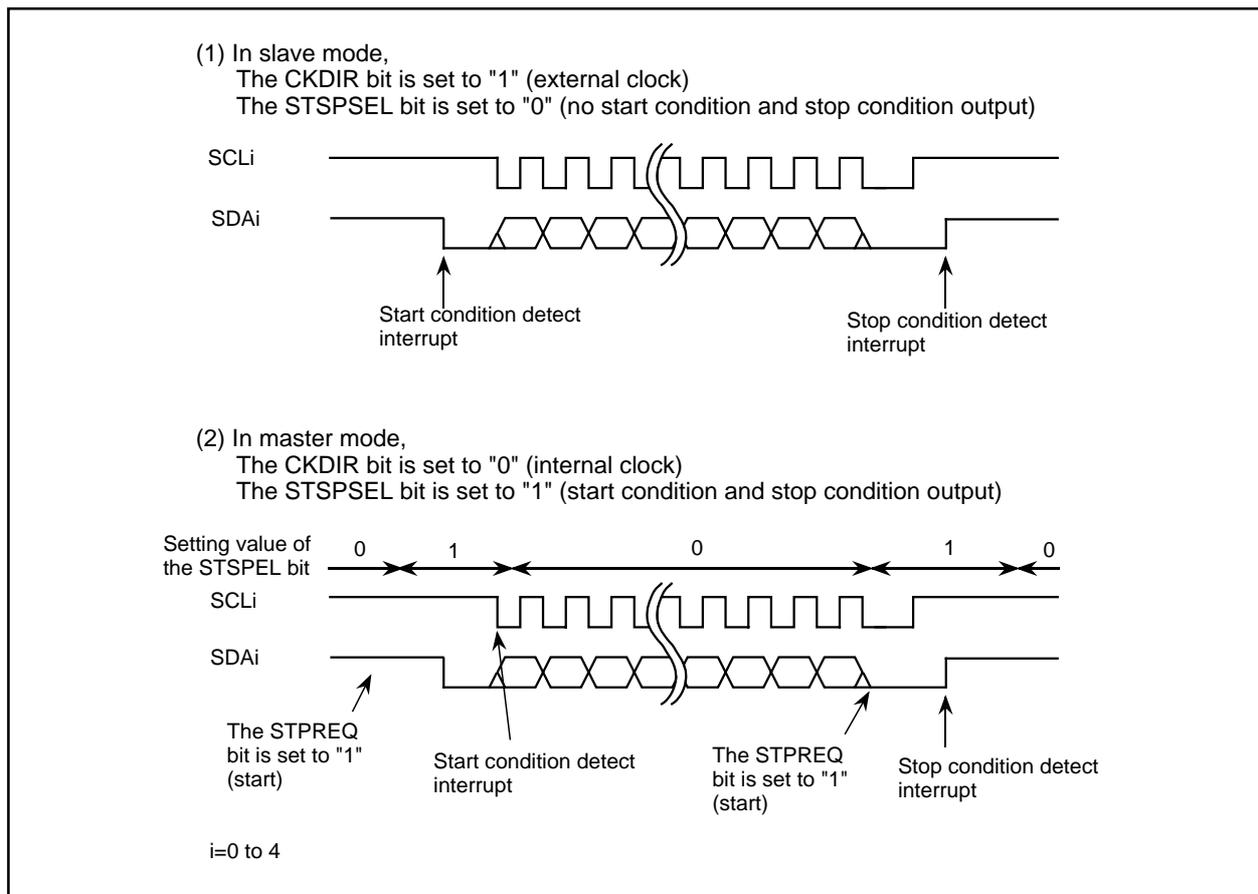

Figure 16.22 STSPSEL Bit Function

16.3.3 Arbitration

The ABC bit in the UiSMR register (i=0 to 4) determines an update timing for the ABT bit in the UiRB register. On the rising edge of the SCLi pin, the microcomputer determines whether a transmit data matches data input to the SDAi pin.

When the ABC bit is set to "0" (update per bit), the ABT bit is set to "1" (detected-arbitration is lost) as soon as a data discrepancy is detected. The ABT bit is set to "0" (not detected-arbitration is won) if not detected. When the ABC bit is set to "1" (update per byte), the ABT bit is set to "1" on the falling edge of the ninth bit of the transfer clock if any discrepancy is detected. When the ABT bit is updated per byte, set the ABT bit to "0" between an ACK detection in the first byte data and the next byte data to be transferred. When the ALS bit in the UiSMR2 register is set to "1" (SDA output stop enabled), the arbitration lost occurs. As soon as the ABT bit is set to "1", the SDAi pin is placed in a high-impedance state.

16.3.4 Transfer Clock

The transfer clock transmits and receives data as is shown in Figure 16.20.

The CSC bit in the UiSMR2 register (i=0 to 4) synchronizes an internally generated clock (internal SCLi) with the external clock applied to the SCLi pin. When the CSC bit is set to "1" (clock synchronous enabled) and the internal SCLi is held high ("H"), the internal SCLi become low ("L") if signal applied to the SCLi pin is on the falling edge. Value of the UiBRG register is reloaded to start counting for low level. A counter stops when the SCLi pin is held "L" and then the internal SCLi changes "L" to "H". Counting is resumed when the SCLi pin become "H". The transfer clock of UARTi is equivalent to the AND for signals from the internal SCLi and the SCLi pin.

The transfer clock is synchronized between a half cycle before the falling edge of first bit of the internal SCLi and the rising edge of the ninth bit. Select the internal clock as the transfer clock while the CSC bit is set to "1".

The SWC bit in the UiSMR2 register determines whether the SCLi pin is fixed to be an "L" signal output on the falling edge of the ninth cycle of the transfer clock or not.

When the SCLHI bit in the UiSMR4 register is set to "1" (enabled), a SCLi output stops when a stop condition is detected (high-impedance).

When the SWC2 bit in the UiSMR2 register is set to "1" (0 output), the SCLi pin forcibly outputs an "L" signal while transmitting and receiving. The fixed "L" signal applied to the SCLi pin is cancelled by setting the SWC2 bit to "0" (transfer clock) and the transfer clock input to and output from the SCLi pin are provided.

When the CKPH bit in the UiSMR3 register is set to "1" and the SWC9 bit in the UiSMR4 register is set to "1" (SCL "L" hold enabled), the SCLi pin is fixed to be an "L" signal output on the next falling edge after the ninth bit of the clock. The fixed "L" signal applied to the SCLi pin is cancelled by setting the SWC9 bit to "0" (SCL "L" hold disabled).

16.3.5 SDA Output

Values output set in bits 7 to 0 (D7 to D0) in the UiTB register (i=0 to 4) are provided in descending order from D7. The ninth bit (D8) is ACK or NACK.

Set the default value of SDAi transmit output when the IICM bit is set to "1" (I²C mode) and the SMD2 to SMD0 bits in the UiMR register are set to "0002" (serial I/O disabled).

The DL2 to DL0 bits in the UiSMR3 register determine no delay in the SDAi output or a delay of 2 to 8 UiBRG register count source cycles.

When the SDHI bit in the UiSMR2 register is set to "1" (SDA output disabled), the SDAi pin is forcibly placed in a high-impedance state. Do not set the SDHI bit on the rising edge of the UARTi transfer clock. The ABT bit in the UiRB register may be set to "1" (detected).

16.3.6 SDA Input

When the IICM2 bit in the UiSMR2 register (i=0 to 4) is set to "0", the first eight bits of received data are stored into bits 7 to 0 (D7 to D0) in the UiRB register. The ninth bit (D8) is ACK or NACK.

When the IICM2 bit is set to "1", the first seven bits (D7 to D1) of received data are stored into bits 6 to 0 in the UiRB register. Store the eighth bit (D0) into bit 8 in the UiRB register.

If the IICM2 bit is set to "1" and the CKPH bit in the UiSMR3 register is set to "1", the same data as that of when setting the IICM2 bit to "0" can be read. To read the data, read the UiRB register after the rising edge of the ninth bit of the transfer clock.

16.3.7 ACK, NACK

When the STPSEL bit in the UiSMR4 register (i=0 to 4) is set to "0" (serial I/O circuit selected) and the ACKC bit in the UiSMR4 register is set to "1" (ACK data output), the SDAi pin provides the value output set in the ACKD bit in the UiSMR4 register.

If the IICM2 bit is set to "0", the NACK interrupt request is generated when the SDAi pin is held high ("H") on the rising edge of the ninth bit of the transfer clock. The ACK interrupt request is generated when the SDAi pin is held low ("L") on the rising edge of the ninth bit of the transfer clock.

When ACK is selected to generate a DMA request, the DMA transfer is activated by an ACK detection.

16.3.8 Transmit and Receive Reset

When the STC bit in the UiSMR2 register (i=0 to 4) is set to "1" (UARTi initialization enabled) and a start condition is detected,

- the transmit shift register is reset and the content of the UiTB register is transferred to the transmit shift register. The first bit starts transmitting when the next clock is input. UARTi output value remains unchanged between when the clock is applied and when the first bit data output is provided. The value remains the same as when start condition was detected.
- the receive shift register is reset and the first bit start receiving when the next clock is applied.
- the SWC bit is set to "1" (SCL wait output enabled). The SCLi pin becomes "L" on the falling edge of the ninth bit of the transfer clock.

If UARTi transmission and reception are started with this function, the TI bit in the UiC1 register remains unchanged. Select the external clock as the transfer clock when using this function.

16.4 Special Mode 2

In special mode 2, serial communication between one or multiple masters and multiple slaves is available. The \overline{SSi} input pin ($i=0$ to 4) controls the serial bus communication. Table 16.19 lists specifications of special mode 2. Table 16.20 lists register settings. Tables 16.21 to 16.23 list pin settings.

Table 16.19 Special Mode 2 Specifications

Item	Specification
Transfer Data Format	Transfer data : 8 bits long
Transfer Clock	<ul style="list-style-type: none"> The CKDIR bit in the UiMR register ($i=0$ to 4) is set to "0" (internal clock selected): $f_j/2(m+1)$ $f_j = f_1, f_8, f_{2n}^{(1)}$ m: setting value of the UiBRG register, 0016 to FF16 The CKDIR bit to "1" (external clock selected) : input from the CLKi pin
Transmit/Receive Control	\overline{SSi} input pin function
Transmit Start Condition	To start transmitting, the following requirements must be met ⁽²⁾ : <ul style="list-style-type: none"> - Set the TE bit in the UiC1 register to "1" (transmit enabled) - Set the TI bit in the UiC1 register to "0" (data in the UiTB register)
Receive Start Condition	To start receiving, the following requirement must be met ⁽²⁾ : <ul style="list-style-type: none"> - Set the RE bit in the UiC1 register to "1" (receive enabled) - Set the TE bit in the UiC1 register to "1" (transmit enabled) - Set the TI bit in the UiC1 register to "0" (data in the UiTB register)
Interrupt Request Generation Timing	<ul style="list-style-type: none"> While transmitting, the following conditions can be selected: <ul style="list-style-type: none"> - The UiIRS bit in the UiC1 register is set to "0" (no data in a transmit buffer) : when data is transferred from the UiTB register to the UAR<i>Ti</i> transmit register (transmission started) - The UiIRS register is set to "1" (transmission completed): when data transmission from UAR<i>Ti</i> transfer register is completed While receiving When data is transferred from the UAR<i>Ti</i> receive register to the UiRB register (reception completed)
Error Detection	<ul style="list-style-type: none"> • Overrun error⁽³⁾ This error occurs when the seventh bit of the next received data is read before reading the UiRB register • Fault error In master mode, the fault error occurs an "L" signal is applied to the \overline{SSi} pin
Selectable Function	<ul style="list-style-type: none"> • CLK polarity Selectable from the rising edge or falling edge of the transfer clock at transferred data output or input timing • LSB first or MSB first Selectable from data transmission or reception in either bit 0 or in bit 7 • Continuous receive mode Data reception is enabled simultaneously by reading the UiRB register • Serial data logic inverse This function inverses transmitted or received data logically • TxD and RxD I/O polarity inverse TxD pin output and RxD pin input are inversed. All I/O data levels are also inversed • Clock phase Selectable from one of 4 combinations of transfer data polarity and phases • \overline{SSi} input pin function Output pin is placed in a high-impedance state to avoid data conflict between master and other masters or slaves

NOTES:

- The CNT3 to CNT0 bits in the TCS*PR* register select no division ($n=0$) or divide-by-2*n* ($n=1$ to 15).
- To start transmission/reception when selecting the external clock, these conditions must be met after the CKPOL bit in the UiC0 register is set to "0" (data is transmitted on the falling edge of the transfer clock and data is received on the rising edge) and the CLKi pin is held high ("H"), or when the CKPOL bit is set to "1" (Data is transmitted on the rising edge of the transfer clock and data is received on the falling edge) and the CLKi pin is held low ("L").
- If an overrun error occurs, the UiRB register is in an indeterminate state. The IR bit setting in the SiR*IC* register does not change to "1" (interrupt requested).

Table 16.20 Register Settings in Special Mode 2

Register	Bit	Function
UiTB	7 to 0	Set transmit data
UiRB	7 to 0	Received data can be read
	OER	Overflow error flag
UiBRG	7 to 0	Set bit rate
UiMR	SMD2 to SMD0	Set to "0012"
	CKDIR	Set to "0" in master mode or "1" in slave mode
	IOPOL	Set to "0"
UiC0	CLK1, CLK0	Select count source for the UiBRG register
	CRS	Disabled because the CRD bit is set to "1"
	TXEPT	Transfer register empty flag
	CRD	Set to "1"
	NCH	Select the output format of the TxDi pin
	CKPOL	Clock phase can be set by the combination of the CKPOL bit and the CKPH bit in the UiSMR3 register
	UFORM	Select either LSB first or MSB first
UiC1	TE	Set to "1" to enable data transmission and reception
	TI	Transfer buffer empty flag
	RE	Set to "1" to enable data reception
	RI	Reception complete flag
	UIIRS	Select what causes the UARTi transmit interrupt to be generated
	UiRRM	Set to "1" to enable continuous receive mode
	UiLCH, SCLKSTPB	Set to "0"
UiSMR	7 to 0	Set to "0016"
UiSMR2	7 to 0	Set to "0016"
UiSMR3	SSE	Set to "1"
	CKPH	Clock phase can be set by the combination of the CKPH bit and the CKPOL bit in the UiC0 register
	DINC	Set to "0" in master mode or "1" in slave mode
	NODC	Set to "0"
	ERR	Fault error flag
	7 to 5	Set to "0002"
UiSMR4	7 to 0	Set to "0016"

i=0 to 4

P96	TxD4 output (master)	PS3_6=1	–	PSC3_6=0	–
	SRxD4 input (slave)	PS3_6=0	PSL3_6=0	–	PD9_6=0
P97	RxD4 input (master)	PS3_7=0	–	–	PD9_7=0
	STxD4 output (slave)	PS3_7=1	PSL3_7=1	–	–

NOTE:

1. Set the PD9 and PS3 registers immediately after the PRC2 bit in the PRCR register is set to "1" (write enabled). Do not generate an interrupt or a DMA transfer between the instruction to set to the PRC2 bit to "1" and the instruction to set the PD9 and PS3 registers.

16.4.1 \overline{SS}_i Input Pin Function (i=0 to 4)

When the SSE bit in the UiSMR3 register is set to "1" (\overline{SS} function enabled), the special mode 2 is selected, activating the pin function.

The DINC bit in the UiSMR3 register determines which microcomputer performs as master or slave. When multiple microcomputers perform as the masters (multi-master system), the \overline{SS}_i pin setting determines which master microcomputer is active and when.

16.4.1.1 When Setting the DINC Bit to "1" (Slave Mode)

When a high-level ("H") signal is applied to the \overline{SS}_i pin, the STxDi and SRxDi pins are placed in a high-impedance state and the transfer clock applied to the CLKi pin is ignored. When a low-level ("L") signal is applied to the \overline{SS}_i input pin, the transfer clock input is valid and serial communication is enabled.

16.4.1.2 When Setting the DINC Bit to "0" (Master Mode)

When using the \overline{SS}_i pin function in master mode, set the UiIRS bit in the UiC1 register to "1" (transmission completed).

When an "H" signal is applied to the \overline{SS}_i pin, serial communication is available due to transmission privilege. The master provides the transfer clock output. When an "L" signal is applied to the \overline{SS}_i pin, it indicates that another master is active. The TxDi and CLKi pins are placed in high-impedance states and the ERR bit in the UiSMR3 register is set to "1" (fault error). Use the transmit complete interrupt routine to verify the ERR bit state.

To resume the serial communication after the fault error occurs, set the ERR bit to "0" while applying the "H" signal to the \overline{SS}_i pin. The TxDi and CLKi pins become ready for signal outputs.

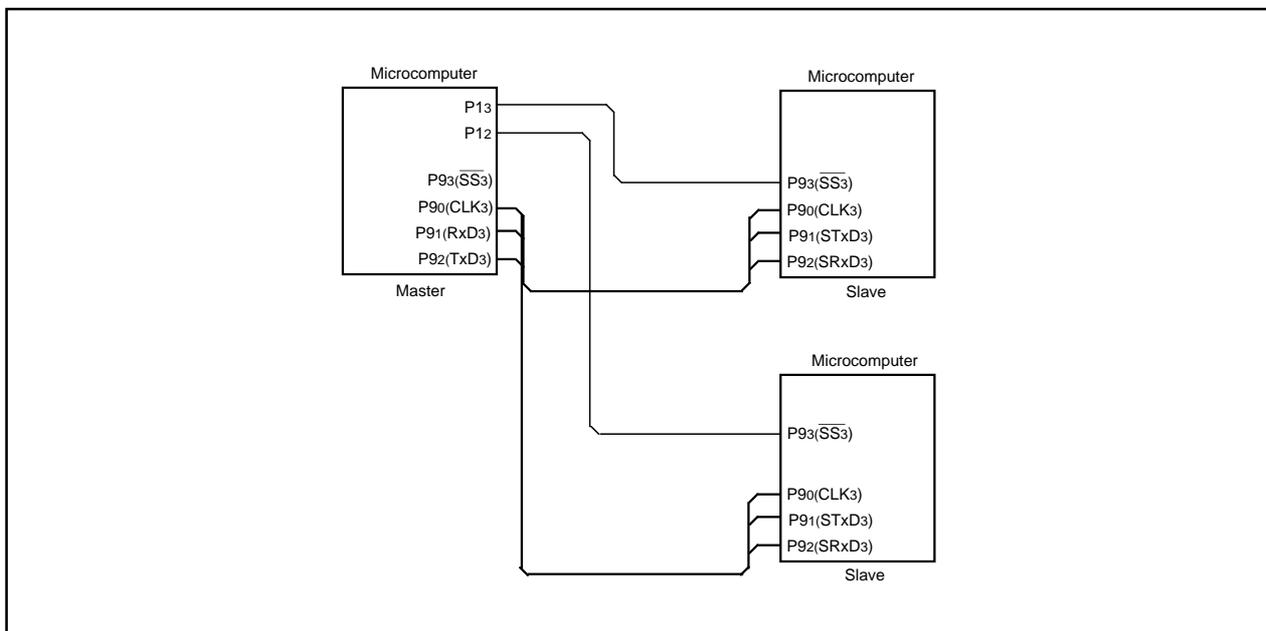

Figure 16.23 Serial Bus Communication Control with SS Pin

16.4.2 Clock Phase Setting Function

The CKPH bit in the UiSMR3 register (i=0 to 4) and the CKPOL bit in the UiC0 register select one of four combinations of transfer clock polarity and phases.

The transfer clock phase and polarity must be the same between the master and the slave involved in the transfer.

16.4.2.1 When setting the DINC Bit to "0" (Master (Internal Clock))

Figure 16.24 shows transmit and receive timing.

16.4.2.2 When Setting the DINC Bit to "1" (Slave (External Clock))

When the CKPH bit is set to "0" (no clock delay) and the \overline{SSi} input pin is held high ("H"), the STxDi pin is placed in a high-impedance state. When the \overline{SSi} input pin becomes low ("L"), conditions to start a serial transfer are met, but output is indeterminate. The serial transmission is synchronized with the transfer clock. Figure 16.25 shows the transmit and receive timing.

When the CKPH bit is set to "1" (clock delay) and the \overline{SSi} input pin is held high, the STxDi pin is placed in a high-impedance state. When the \overline{SSi} pin becomes low, the first data is output. The serial transmission is synchronized with the transfer clock. Figure 16.26 shows the transmit and receive timing.

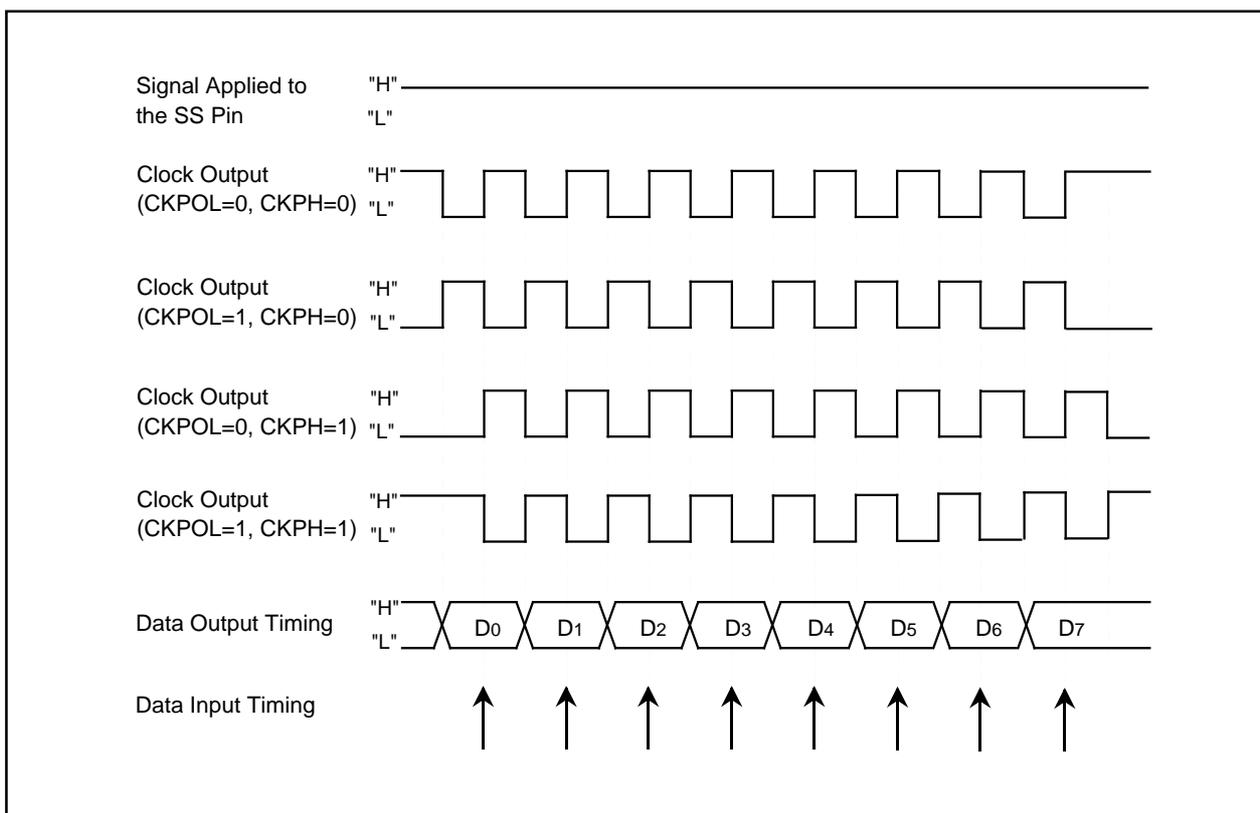

Figure 16.24 Transmit and Receive Timing in Master Mode (Internal Clock)

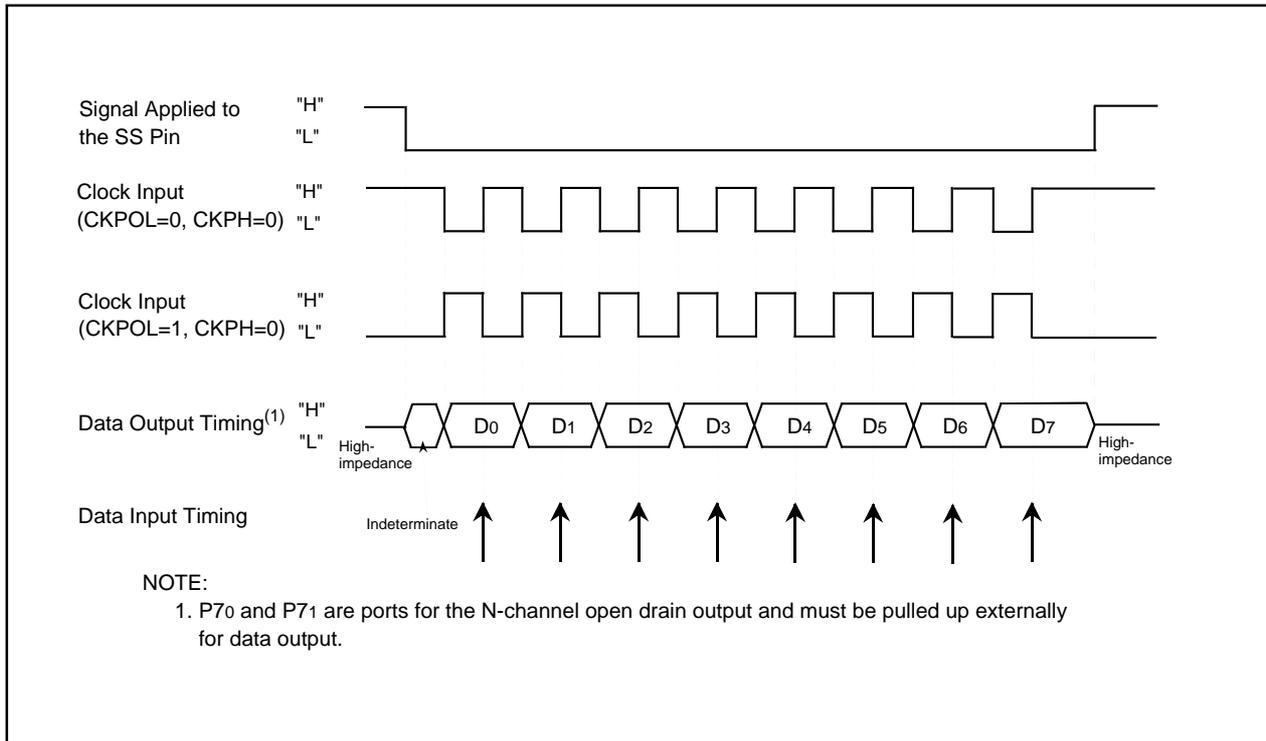

Figure 16.25 Transmit and Receive Timing in Slave Mode (External Clock) (CKPH=0)

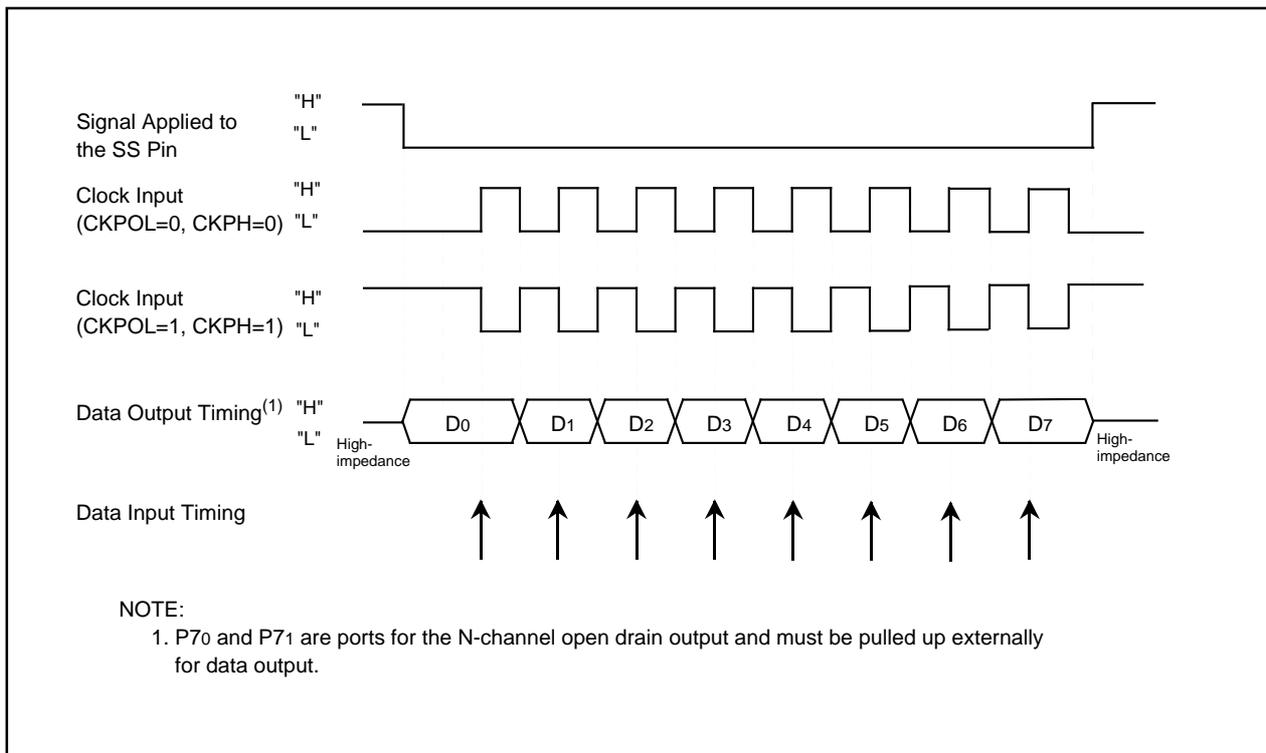

Figure 16.26 Transmit and Receive Timing in Slave Mode (External Clock) (CKPH=1)

16.5 Special Mode 3 (GCI Mode)

In GCI mode, the external clock is synchronized with the transfer clock used in the clock synchronous serial I/O mode.

Table 16.24 lists specifications of GCI mode. Table 16.25 lists registers settings. Tables 16.26 to 16.28 list pin settings.

Table 16.24 GCI Mode Specifications

Item	Specification
Transfer Data Format	Transfer data : 8 bits long
Transfer Clock	The CKDIR bit in the UiMR register (i=0 to 4) is set to "1" (external clock selected): input from the CLKi pin
Clock Synchronization Function	Trigger signal input from the $\overline{\text{CTS}}_i$ pin
Transmit/Receive Start Condition	To start data transmission and reception, meet the following conditions and then apply a trigger signal to the $\overline{\text{CTS}}_i$ pin: <ul style="list-style-type: none"> - Set the TE bit in the UiC1 register to "1" (transmit enabled) - Set the RE bit in the UiC1 register to "1" (receive enabled) - Set the TI bit in the UiC1 register to "0" (Data in the UiTB register)
Interrupt Request Generation Timing	<ul style="list-style-type: none"> • While transmitting, the following condition can be selected: <ul style="list-style-type: none"> - The UiIRS bit in the UiC1 register is set to "0" (UiTB register empty): when data is transferred from the UiTB register to the UARTi transmit register (transmission started) - The UiIRS bit is set to "1" (Transmit completed): when a data transmission from the UARTi transfer register is completed • While receiving, when data is transferred from the UARTi receive register to the UiRB register (reception completed)
Error Detection	<p>Overflow error⁽¹⁾</p> <p>This error occurs when the seventh bit of the next received data is read before reading the UiRB register.</p>

NOTE:

1. If an overflow error occurs, the UiRB register is indeterminate. The IR bit setting in the SiRIC register does not change to "1" (interrupt requested).

P97	RxD4 input	PS3_7=0	–	–	PD9_7=0

NOTES:

1. Set the PD9 and PS3 registers immediately after the PRC2 bit in the PRCR register is set to "1" (write enabled). Do not generate an interrupt or a DMA transfer between the instruction to set to the PRC2 bit to "1" and the instruction to set the PD9 and PS3 registers.
2. CTS input is used for a trigger signal input.

To generate the internal clock synchronized with the external clock, set the SU1HIM bit in the UiSMR2 register ($i=0$ to 4) and the SCLKDIV bit in the UiSMR register to values shown in Table 16.29. Then apply a trigger signal to the $\overline{\text{CTS}}_i$ pin. Either the same clock cycle as the external clock or external clock divided by two can be selected as the transfer clock. The SCLKSTPB bit in the UiC1 register controls the transfer clock. Set the SCLKSTPB bit accordingly, to start or stop the transfer clock during an external clock operation. Figure 16.27 shows an example of the clock-divided synchronous function.

Table 16.29 Clock-Divided Synchronous Function Select

SCLKDIV Bit in UiSMR Register	SU1HIM Bit in UiSMR2 Register	Clock-Divided Synchronous Function	Example of Waveform
0	0	Not synchronized	-
0	1	Same division as the external clock	A in Figure 16.27
1	0 or 1	Same division as the external clock divided by 2	B in Figure 16.27

$i=0$ to 4

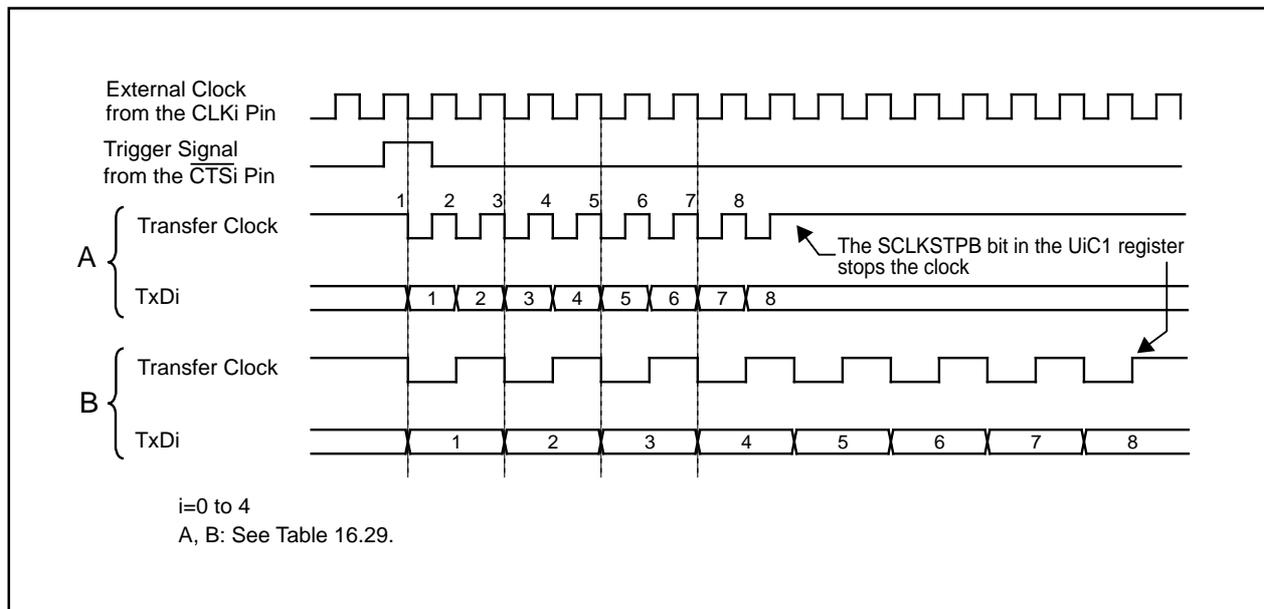

Figure 16.27 Clock-Divided Synchronous Function

16.6 Special Mode 4 (IE Mode)

In IE mode, devices connected with the IEBus can communicate in UART mode.

Table 16.30 lists register settings. Tables 16.31 to 16.33 list pin settings.

Table 16.30 Register Settings in IE Mode

Register	Bit	Function
UiTB	8 to 0	Set transmit data
UiRB	8 to 0	Received data can be read
	OER, FER, PER, SUM	Error flags
UiBRG	7 to 0	Set bit rate
UiMR	SMD2 to SMD0	Set to "1102"
	CKDIR	Select the internal clock or external clock
	STPS	Set to "0"
	PRY	Disabled because the PRYE bit is set to "0"
	PRYE	Set to "0"

P70 ⁽¹⁾	TxD2 output	PS1_0=1	PSL1_0=0	PSC_0=0	–
P71 ⁽¹⁾	RxD2 input	PS1_1=0	–	–	PD7_1=0
P72	CLK2 input	PS1_2=0	–	–	PD7_2=0
	CLK2 output	PS1_2=1	PSL1_2=0	PSC_2=0	–

NOTE:

1. P70 and P71 are ports for the N-channel open drain output.

Table 16.33 Pin Settings (3)

Port	Function	Setting			
		PS3 Register ⁽¹⁾	PSL3 Register	PSC3 Register	PD9 Register ⁽¹⁾
P90	CLK3 input	PS3_0=0	–	–	PD9_0=0
	CLK3 output	PS3_0=1	–	–	–
P91	RxD3 input	PS3_1=0	–	–	PD9_1=0
P92	TxD3 output	PS3_2=1	PSL3_2=0	–	–
P95	CLK4 input	PS3_5=0	PSL3_5=0	–	PD9_5=0
	CLK4 output	PS3_5=1	–	–	–
P96	TxD4 output	PS3_6=1	–	PSC3_6=0	–
P97	RxD4 input	PS3_7=0	–	–	PD9_7=0

NOTE:

1. Set the PD9 and PS3 registers immediately after the PRC2 bit in the PRCR register is set to "1" (write enabled). Do not generate an interrupt or a DMA transfer between the instruction to set to the PRC2 bit to "1" and the instruction to set the PD9 and PS3 registers.

If the output signal level of the TxDi pin (i=0 to 4) differs from the input signal level of the RxDi pin, an interrupt request is generated.

UART0 and UART3 are assigned software interrupt number 40. UART1 and UART4 are assigned number 41. When using the bus conflict detect function of UART0 or UART3, of UART1 or UART4, set the IFSR6 bit and the IFSR7 bit in the IFSR register accordingly.

When the ABSCS bit in the UiSMR register is set to "0" (rising edge of the transfer clock), it is determined, on the rising edge of the transfer clock, if the output level of the TxD pin and the input level of the RxD pin match. When the ABSCS bit is set to "1" (timer Aj underflow), it is determined when the timer Aj (timer A3 in UART0, timer A4 in UART1, timer A0 in UART2, timer A3 in UART3, the timer A4 in UART4) counter overflows. Use the timer Aj in one-shot timer mode.

When the ACSE bit in the UiSMR register is set to "1" (automatic clear at bus conflict) and the IR bit in the BCNiIC register to "1" (discrepancy detected), the TE bit in the UiC1 register is set to "0" (transmit disabled).

When the SSS bit in the UiSMR register is set to "1" (synchronized with RxDi), data is transmitted from the TxDi pin on the falling edge of the RxDi pin. Figure 16.28 shows bits associated with the bus conflict detect function.

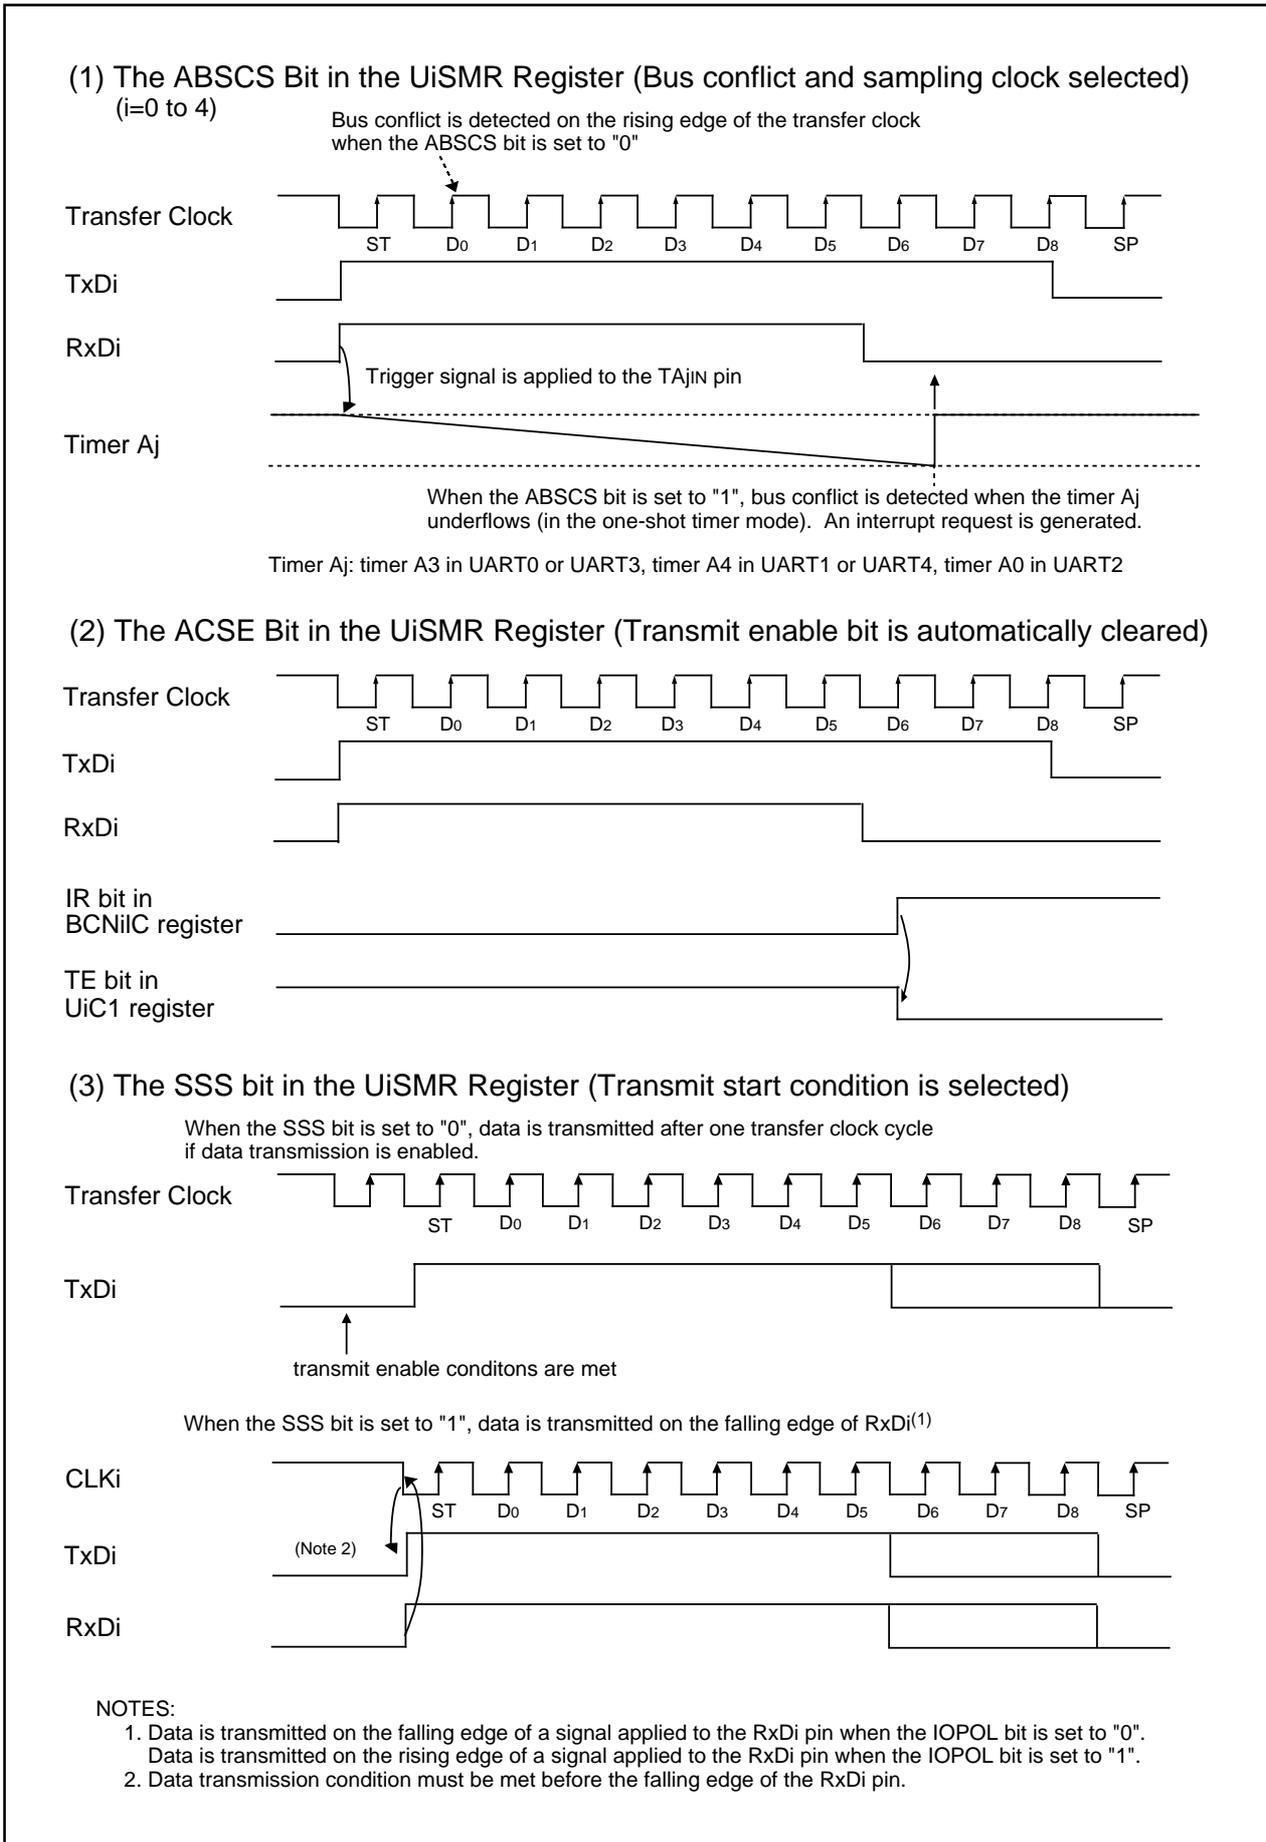

Figure 16.28 Bit Function Related Bus Conflict Detection

16.7 Special Mode 5 (SIM Mode)

In SIM mode, SIM interface devices can communicate in UART mode. Both direct and inverse formats are available and a low-level ("L") signal output can be provided from the TxDi pin (i=0 to 4) when a parity error is detected.

Table 16.34 lists specifications of SIM mode. Table 16.35 lists register settings. Tables 16.36 to 16.38 list pin settings.

Table 16.34 SIM Mode Specifications

Item	Specification
Transfer Data Format	<ul style="list-style-type: none"> • Transfer data: 8-bit UART mode • In direct format Parity: Even Data logic: Direct Transfer format: LSB first <ul style="list-style-type: none"> • One stop bit • In inverse format Parity: Odd Data logic: Inverse Transfer format: MSB first
Transfer Clock	<ul style="list-style-type: none"> • The CKDIR bit in the UiMR register (i=0 to 4) is "0" (internal clock selected): $f_i/16(m+1)^{f_i}$ $f_i = f_1, f_8, f_{2n}^{(2)}$ m: setting value of the UiBRG register, 00₁₆ to FF₁₆ Do not set the CKDIR bit to "1" (external clock selected)
Transmit/Receive Control	The CRD bit in the UiC0 register is set to "1" ($\overline{\text{CTS}}$, $\overline{\text{RTS}}$ function disabled)
Other Setting Items	The UiIRS bit in the UiC1 register is set to "1" (transmission completed)
Transmit Start Condition	To start transmitting, the following requirements must be met: <ul style="list-style-type: none"> - Set the TE bit in the UiC1 register to "1" (transmit enabled) - Set the TI bit in the UiC1 register to "0" (data in the UiTB register)
Receive Start Condition	To start receiving, the following requirements must be met: <ul style="list-style-type: none"> - Set the RE bit in the UiC1 register to "1" (receive enabled) - Detect the start bit
Interrupt Request Generation Timing	<ul style="list-style-type: none"> • While transmitting, <ul style="list-style-type: none"> -The UiIRS bit is set to "1" (transmission completed): when data transmission from the UARTi transfer register is completed • While receiving, <ul style="list-style-type: none"> when data is transferred from the UARTi receive register to the UiRB register (reception completed)
Error Detection	<ul style="list-style-type: none"> • Overrun error⁽¹⁾ <ul style="list-style-type: none"> This error occurs when the eighth bit of the next data is received before reading the UiRB register • Framing error <ul style="list-style-type: none"> This error occurs when the number of the stop bit set is not detected • Parity error <ul style="list-style-type: none"> This error occurs when the number of "1" in parity bit and character bits differs from the number set • Error sum flag <ul style="list-style-type: none"> The SUM bit is set to "1" when an overrun error, framing error or parity error occurs

NOTES:

1. If an overrun error occurs, the UiRB register is indeterminate. The IR bit setting in the SiRIC register does not change to "1" (interrupt requested).
2. The CNT3 to CNT0 bits in the TCSPR register select no division (n=0) or divide-by-2ⁿ (n=1 to 15).

Table 16.35 Register Settings in SIM Mode

Register	Bit	Function
UiTB	7 to 0	Set transmit data
UiRB	7 to 0	Received data can be read
	OER, FER, PER, SUM	Error flags
UiBRG	7 to 0	Set bit rate
UiMR	SMD2 to SMD0	Set to "1012"
	CKDIR	Set to "0"
	STPS	Set to "0"
	PRY	Set to "1" for direct format or "0" for inverse format
	PRYE	Set to "1"
	IOPOL	Set to "0"
UiC0	CLK1, CLK0	Select count source for the UiBRG register
	CRS	Disabled because the CRD bit is set to "1"
	TXEPT	Transfer register empty flag
	CRD	Set to "1"
	NCH	Set to "1"
	CKPOL	Set to "0"
	UFORM	Set to "0" for direct format or "1" for inverse format
UiC1	TE	Set to "1" to enable data transmission
	TI	Transfer buffer empty flag
	RE	Set to "1" to enable data reception
	RI	Reception complete flag
	UiIRS	Set to "1"
	UiRRM	Set to "0"
	UiLCH	Set to "0" for direct format or "1" for inverse format
	UiERE	Set to "1"
UiSMR	7 to 0	Set to "0016"
UiSMR2	7 to 0	Set to "0016"
UiSMR3	7 to 0	Set to "0016"
UiSMR4	7 to 0	Set to "0016"

i=0 to 4

P71 ⁽¹⁾	RxD2 input	PS1_1=0	–	–	PD7_1=0

NOTE:

1. P70 and P71 are ports for the N-channel open drain output.

Table 16.38 Pin Settings (3)

Port	Function	Setting			
		PS3 Register ⁽¹⁾	PSL3 Register	PSC3 Register	PD9 Register ⁽¹⁾
P91	RxD3 input	PS3_1=0	–		PD9_1=0
P92	TxD3 output	PS3_2=1	PSL3_2=0		–
P96	TxD4 output	PS3_6=1	–	PSC3_6=0	–
P97	RxD4 input	PS3_7=0	–		PD9_7=0

NOTE:

1. Set the PD9 and PS3 registers immediately after the PRC2 bit in the PRCR register is set to "1" (write enabled). Do not generate an interrupt or a DMA transfer between the instruction to set to the PRC2 bit to "1" and the instruction to set the PD9 and PS3 registers.

Figure 16.29 shows an example of a SIM interface operation. Figure 16.30 shows an example of a SIM interface connection. Connect the TxDi pin to the RxDi pin for a pull-up.

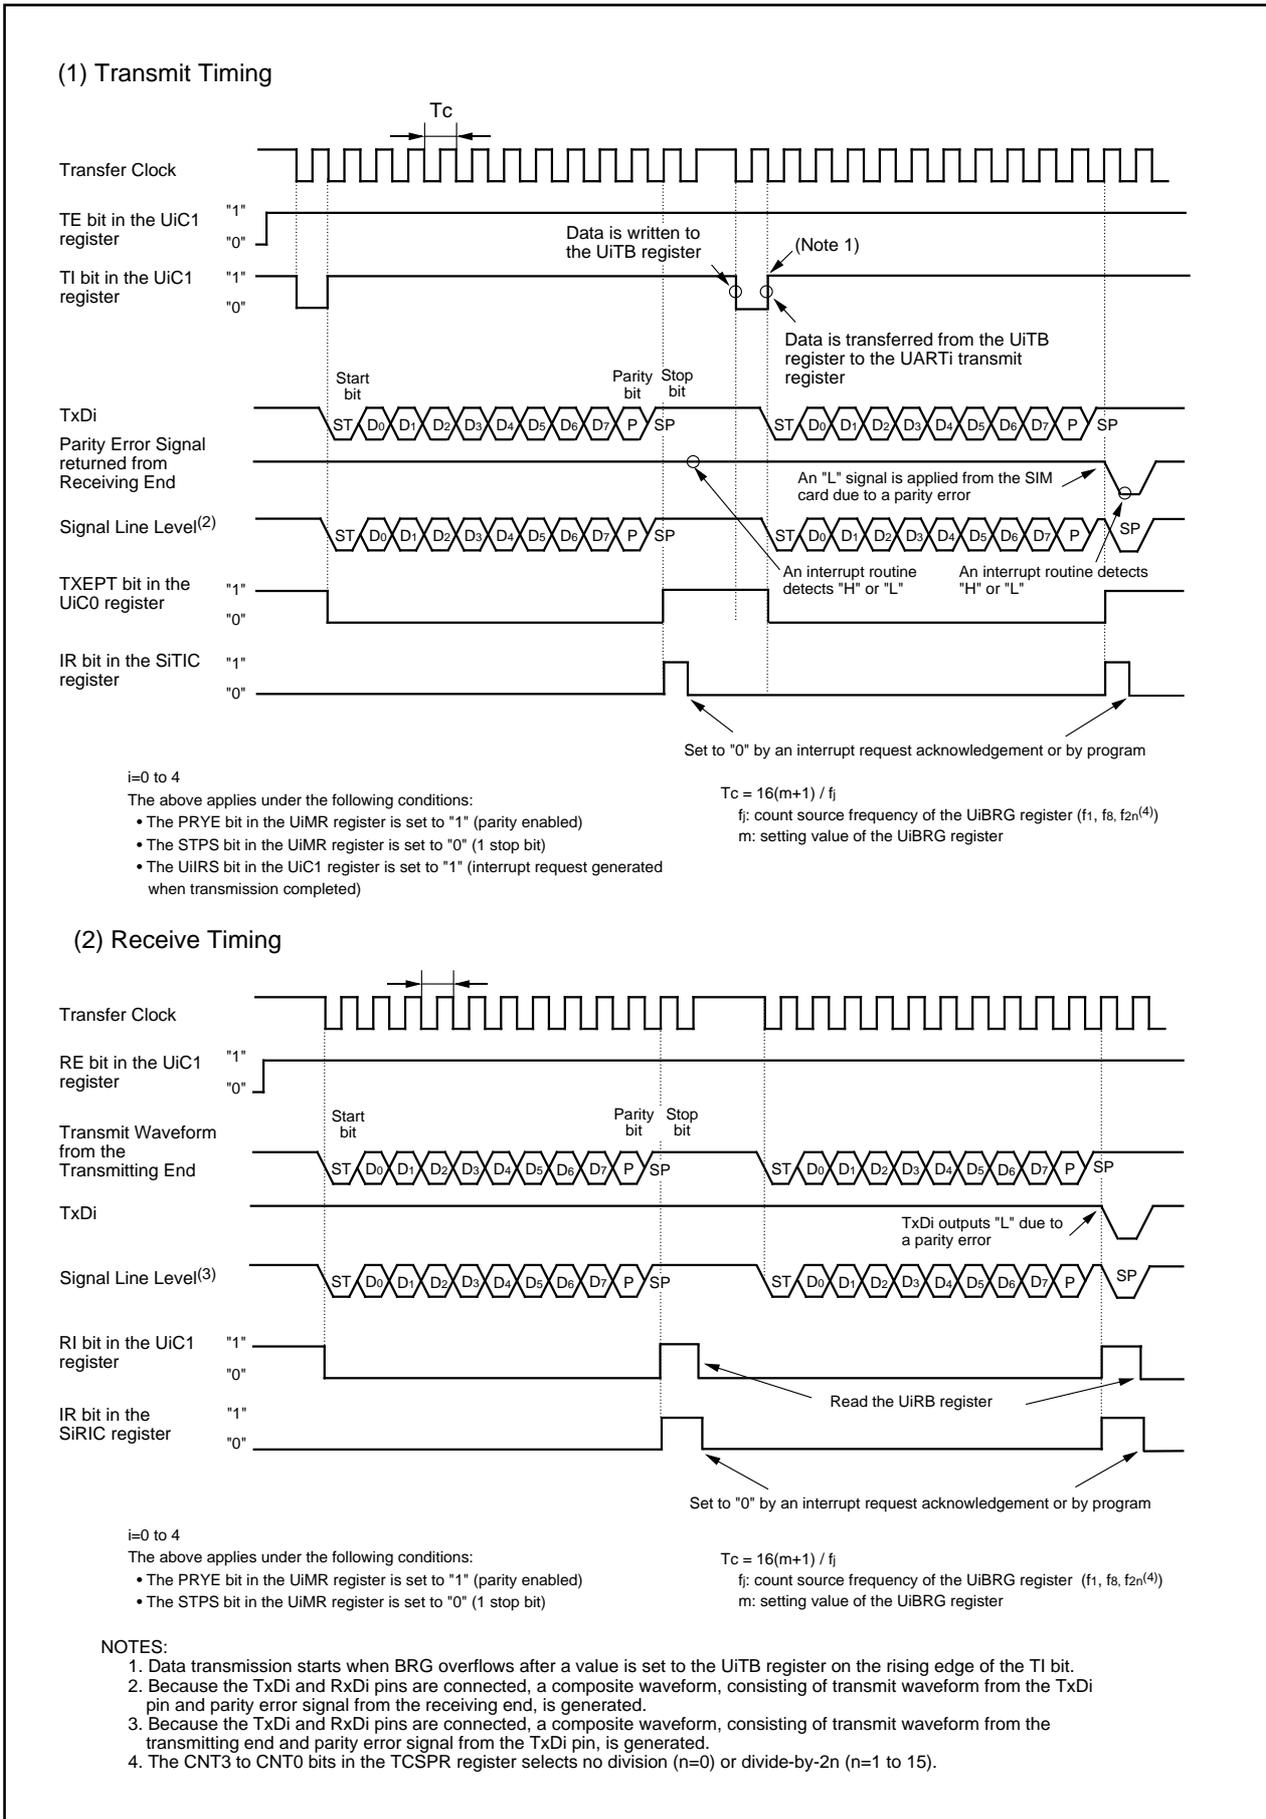

Figure 16.29 SIM Interface Operation

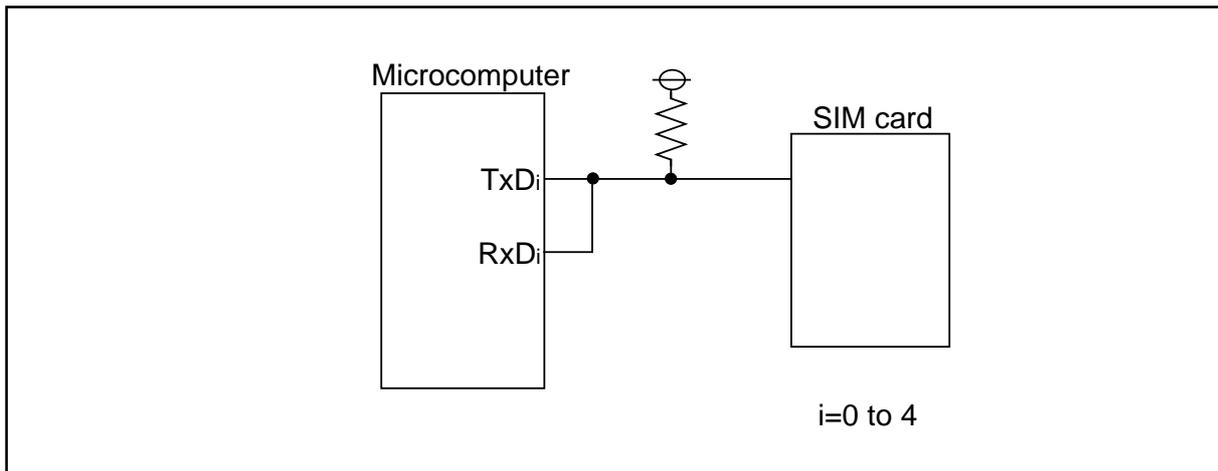

Figure 16.30 SIM Interface Connection

16.7.1 Parity Error Signal

16.7.1.1 Parity Error Signal Output Function

When the UiERE bit in the UiC1 register (i=0 to 4) is set to "1" (output), the parity error signal output can be provided. The parity error signal output is provided when a parity error is detected upon receiving data. A low-level ("L") signal output is provided from the TxDi pin in the timing shown in Figure 16.31. When reading the UiRB register during a parity error output, the PER bit in the UiRB register is set to "0" (no error occurs) and a high-level ("H") signal output is again provided simultaneously.

16.7.1.2 Parity Error Signal

To determine whether the parity error signal is output, the port that shares a pin with the RxDi pin is read by using an end-of-transmit interrupt routine.

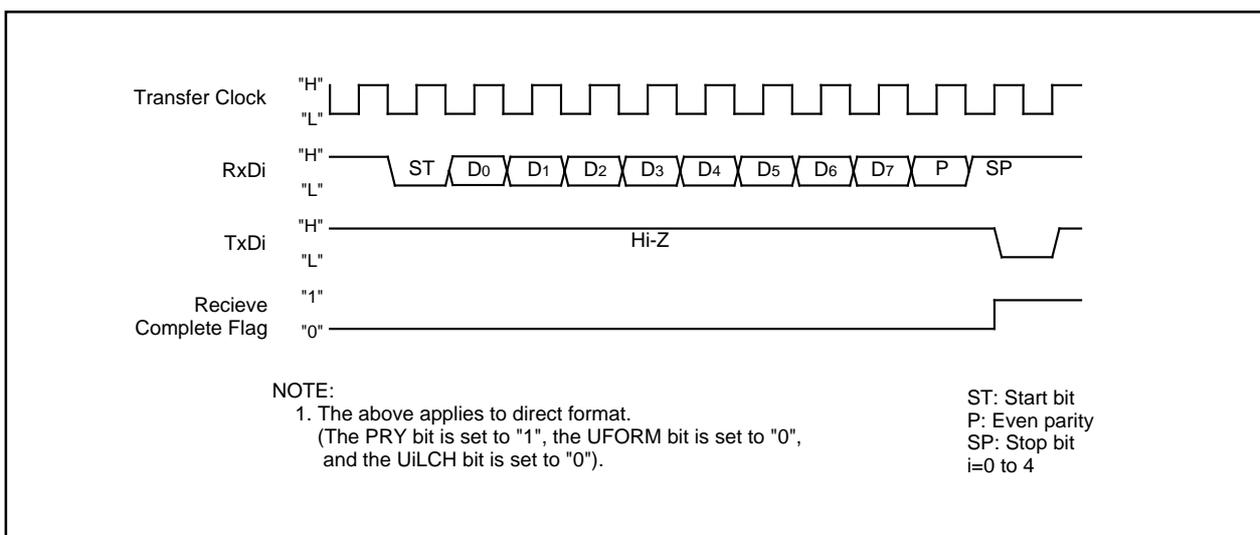

Figure 16.31 Parity Error Signal Output Timing (LSB First)

16.7.2 Format

16.7.2.1 Direct Format

Set the PRYE bit in the UiMR register ($i=0$ to 4) to "1" (parity enabled), the PRY bit to "1" (even parity), the UFORM bit in the UiC0 register to "0" (LSB first) and the UiLCH bit in the UiC1 register to "0" (not inverted). When data are transmitted, data set in the UiTB register are transmitted with the even-numbered parity, starting from D0. When data are received, received data are stored in the UiRB register, starting from D0. The even-numbered parity determines whether a parity error occurs.

16.7.2.2 Inverse Format

Set the PRYE bit to "1", the PRY bit to "0" (odd parity), the UFORM bit to "1" (MSB first) and the UiLCH bit to "1" (inverted). When data are transmitted, values set in the UiTB register are logically inverted and are transmitted with the odd-numbered parity, starting from D7. When data are received, received data are logically inverted to be stored in the UiRB register, starting from D7. The odd-numbered parity determines whether a parity error occurs.

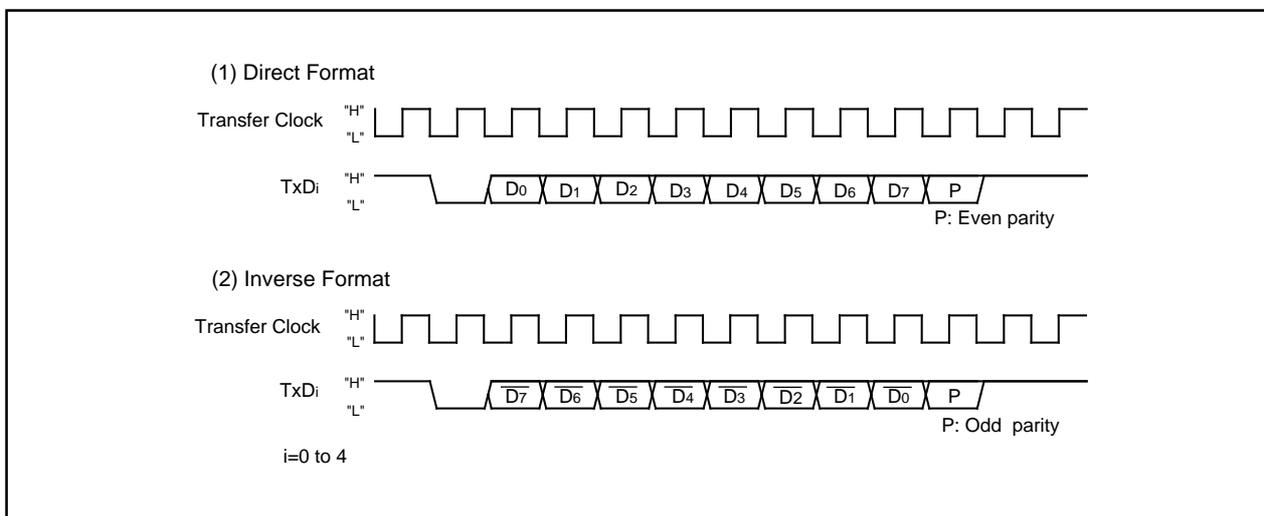

Figure 16.32 SIM Interface Format

17. A/D Converter

The A/D converter consists of one 10-bit successive approximation A/D converter with a capacitive coupling amplifier.

The result of an A/D conversion is stored into the A/D registers corresponding to selected pins. It is stored into the AD00 register only when DMAC operating mode is entered.

Table 17.1 lists specifications of the A/D converter. Figure 17.1 shows a block diagram of the A/D converter. Figures 17.2 to 17.6 show registers associated with the A/D converter.

Table 17.1 A/D Converter Specifications

Item	Specification
A/D Conversion Method	Successive approximation (with a capacitive coupling amplifier)
Analog Input Voltage ⁽¹⁾	0V to AVCC (VCC1)
Operating Clock, ϕ_{AD} ⁽²⁾	fAD, fAD/2, fAD/3, fAD/4, fAD/6, fAD/8
Resolution	8 bits or 10 bits
Operating Mode	One-shot mode, repeat mode, single sweep mode, repeat sweep mode 0, repeat sweep mode 1
Analog Input Pins ⁽³⁾	10 pins 8 pins for AN0 to AN7 2 extended input pins (ANEX0 and ANEX1)
A/D Conversion Start Condition	<ul style="list-style-type: none"> • Software trigger The ADST bit in the AD0CON0 register is set to "1" (A/D conversion started) by program • External trigger (re-trigger is enabled) When a falling edge is applied to the \overline{ADTRG} pin after the ADST bit is set to "1" by program • Hardware trigger (re-trigger is enabled) The timer B2 interrupt request of the three-phase motor control timer functions (after the ICTB2 counter completes counting) is generated after the ADST bit is set to "1" by program
Conversion Rate Per Pin	<ul style="list-style-type: none"> • Without the sample and hold function 8-bit resolution : 49 ϕ_{AD} cycles 10-bit resolution : 59 ϕ_{AD} cycles • With the sample and hold function 8-bit resolution : 28 ϕ_{AD} cycles 10-bit resolution : 33 ϕ_{AD} cycles

NOTES:

1. Analog input voltage is not affected by the sample and hold function status.
2. ϕ_{AD} frequency must be under 16 MHz when VCC1=5V.
 ϕ_{AD} frequency must be under 10 MHz when VCC1=3.3V.
Without the sample and hold function, the ϕ_{AD} frequency is 250 kHz or more.
With the sample and hold function, the ϕ_{AD} frequency is 1 MHz or more.
3. AVCC=VREF=VCC1, A/D input voltage (for AN0 to AN7, ANEX0, and ANEX1) \leq VCC1.

17.1 Mode Description

17.1.1 One-shot Mode

In one-shot mode, analog voltage applied to a selected pin is converted to a digital code once. Table 17.2 lists specifications of one-shot mode.

Table 17.2 One-shot Mode Specifications

Item	Specification
Function	The CH2 to CH0 bits in the AD0CON0 register and the OPA1 and OPA0 bits in the AD0CON1 register select a pin. Analog voltage applied to the pin is converted to a digital code once
Start Condition	<ul style="list-style-type: none"> • When the TRG bit in the AD0CON0 register is set to "0" (software trigger), the ADST bit in the AD0CON0 register is set to "1" (A/D conversion starts) by program • When the TRG bit is set to "1" (external trigger, hardware trigger): <ul style="list-style-type: none"> - a falling edge is applied to the \overline{ADTRG} pin after the ADST bit is set to "1" by program - The timer B2 interrupt request of three-phase motor control timer functions (after the ICTB2 register counter completes counting) is generated after the ADST bit is set to "1" by program
Stop Condition	<ul style="list-style-type: none"> • A/D conversion is completed (the ADST bit is set to "0" when the software trigger is selected) • The ADST bit is set to "0" (A/D conversion stopped) by program
Interrupt Request Generation Timing	A/D conversion is completed
Analog Voltage Input Pins	Select one pin from AN0 to AN7, ANEX0, or ANEX1
Reading of A/D Conversion Result	<ul style="list-style-type: none"> • When the DUS bit in the AD0CON3 register is set to "0" (DMAC operating mode disabled), the microcomputer reads the AD0j register (j=0 to 7) corresponding to selected pin • When the DUS bit is set to "1" (DMAC operating mode enabled), do not read the AD00 register. A/D conversion result is stored in the AD00 register after the A/D conversion is completed. DMAC transfers the conversion result to any memory space. Refer to 12. DMAC for DMAC settings

17.1.2 Repeat Mode

In repeat mode, analog voltage applied to a selected pin is repeatedly converted to a digital code. Table 17.3 lists specifications of repeat mode.

Table 17.3 Repeat Mode Specifications

Item	Specification
Function	The CH2 to CH0 bits in the AD0CON0 register and the OPA1 and OPA0 bits in the AD0CON1 register select a pin. Analog voltage applied to the pin is repeatedly converted to a digital code
Start Condition	Same as one-shot mode
Stop Condition	The ADST bit in the AD0CON0 register is set to "0" (A/D conversion stopped) by program
Interrupt Request Generation Timing	<ul style="list-style-type: none"> • When the DUS bit in the AD0CON3 register is set to "0" (DMAC operating mode disabled), no interrupt request is generated. • When DUS bit is set to "1" (DMAC operating mode enabled), an interrupt request is generated every time an A/D conversion is completed.
Analog Voltage Input Pins	Select one pin from AN0 to AN7, ANEX0, or ANEX1
Reading of A/D Conversion Result	<ul style="list-style-type: none"> • When the DUS bit is set to "0", the microcomputer reads the AD0j register (j=0 to 7) corresponding to the selected pin. • When DUS bit is set to "1", do not read the AD00 register. A/D conversion result is stored in the AD00 register after the A/D conversion is completed. DMAC transfers the conversion result to any memory space. <p>Refer to 12. DMAC for DMAC settings</p>

17.1.3 Single Sweep Mode

In single sweep mode, analog voltage that is applied to selected pins is converted one-by-one to a digital code. Table 17.4 lists specifications of single sweep mode.

Table 17.4 Single Sweep Mode Specifications

Item	Specification
Function	The SCAN1 and SCAN0 bits in the AD0CON1 register select pins. Analog voltage applied to the pin is converted one-by-one to a digital code
Start Condition	Same as one-shot mode
Stop Condition	Same as one-shot mode
Interrupt Request Generation Timing	<ul style="list-style-type: none"> • When the DUS bit in the AD0CON3 register is set to "0" (DMAC operating mode disabled), an interrupt request is generated after a sweep is completed. • When DUS bit is set to "1" (DMAC operating mode enabled), an interrupt request is generated every time an A/D conversion is completed
Analog Voltage Input Pins	Select from AN0 and AN1 (2 pins), AN0 to AN3 (4 pins), AN0 to AN5 (6 pins) or AN0 to AN7 (8 pins)
Reading of A/D Conversion Result	<ul style="list-style-type: none"> • When the DUS bit is set to "0", the microcomputer reads the AD0j register (j=0 to 7) corresponding to selected pins • When DUS bit is set to "1", do not read the AD00 register. A/D conversion result is stored in the AD00 register after the A/D conversion is completed. DMAC transfers the conversion result to any memory space. Refer to 12. DMAC for DMAC settings

17.1.4 Repeat Sweep Mode 0

In repeat sweep mode 0, analog voltage applied to selected pins is repeatedly converted to a digital code. Table 17.5 lists specifications of repeat sweep mode 0.

Table 17.5 Repeat Sweep Mode 0 Specifications

Item	Specification
Function	The SCAN1 and SCAN0 bits in the AD0CON1 register select pins. Analog voltage applied to the pins is repeatedly converted to a digital code
Start Condition	Same as one-shot mode
Stop Condition	The ADST bit in the AD0CON0 register is set to "0" (A/D conversion stopped) by program
Interrupt Request Generation Timing	<ul style="list-style-type: none"> • When the DUS bit in the AD0CON3 register is set to "0" (DMAC operating mode disabled), no interrupt request is generated • When DUS bit is set to "1" (DMAC operating mode enabled), an interrupt request is generated every time an A/D conversion is completed
Analog Voltage Input Pins	Select from AN0 and AN1 (2 pins), AN0 to AN3 (4 pins), AN0 to AN5 (6 pins) or AN0 to AN7 (8 pins)
Reading of A/D Conversion Result	<ul style="list-style-type: none"> • When the DUS bit is set to "0", the microcomputer reads the AD0j register (j=0 to 7) corresponding to selected pins • When the DUS bit is set to "1", do not read the AD00 register. A/D conversion result is stored in the AD00 register after the A/D conversion is completed. DMAC transfers the conversion result to any memory space. Refer to 12. DMAC for DMAC settings

17.1.5 Repeat Sweep Mode 1

In repeat sweep mode 1, analog voltage selectively applied to eight pins is repeatedly converted to a digital code. Table 17.6 lists specifications of repeat sweep mode 1.

Table 17.6 Repeat Sweep Mode 1 Specifications

Item	Specification
Function	The SCAN1 and SCAN0 bits in the AD0CON1 register select 8 pins. Analog voltage selectively applied to 8 pins is repeatedly converted to a digital code e.g., When AN _i is selected (i = none, 0, 2, 15), analog voltage is converted to a digital code in the following order: AN ₀ → AN ₁ → AN ₀ → AN ₂ → AN ₀ → AN ₃ etc.
Start Condition	Same as one-shot mode (Any trigger generated during an A/D conversion is invalid)
Stop Condition	The ADST bit is set to "0" (A/D conversion stopped) by program
Interrupt Request Generation Timing	<ul style="list-style-type: none"> • When the DUS bit in the AD0CON3 register is set to "0" (DMAC operating mode disabled), no interrupt request is generated • When DUS bit is set to "1" (DMAC operating mode enabled), an interrupt request is generated every time an A/D conversion is completed
Analog Voltage Input Pins	AN ₀ to AN ₇ (8 pins)
Prioritized Pins	AN ₀ (1 pin), AN ₀ and AN ₁ (2 pins), AN ₀ to AN ₂ (3 pins) or AN ₀ to AN ₃ (4 pins)
Reading of A/D Conversion Result	<ul style="list-style-type: none"> • When the DUS bit is set to "0", the microcomputer reads the AD0_j register (j=0 to 7) corresponding to selected pins • When the DUS bit is set to "1", do not read the AD00 register. A/D conversion result is stored in the AD00 register after the A/D conversion is completed. DMAC transfers the conversion result to any memory space. Refer to 12. DMAC for DMAC settings

17.2 Functions

17.2.1 Resolution Select Function

The BITS bit in the AD0CON1 register determines the resolution. When the BITS bit is set to "1" (10-bit precision), the A/D conversion result is stored into bits 9 to 0 in the AD0j register (j = 0 to 7). When the BITS bit is set to "0" (8-bit precision), the A/D conversion result is stored into bits 7 to 0 in the AD0j register.

17.2.2 Sample and Hold Function

When the SMP bit in the AD0CON2 register is set to "1" (with the sample and hold function), A/D conversion rate per pin increases to $28 \varnothing_{AD}$ cycles for 8-bit resolution and $33 \varnothing_{AD}$ cycles for 10-bit resolution. The sample and hold function is available in all operating modes. Start the A/D conversion after selecting whether the sample and hold function is to be used or not.

17.2.3 Trigger Select Function

The TRG bit in the AD0CON0 register and the TRG0 bit in the AD0CON2 register select the trigger to start the A/D conversion. Table 17.9 lists settings of the trigger select function.

Table 17.9 Trigger Select Function Settings

Bit and Setting		Trigger
AD0CON0 Register	AD0CON2 Register	
TRG = 0	-	Software trigger The A/D0 starts the A/D conversion when the ADST bit in the AD0CON0 register is set to "1"
TRG = 1 ⁽¹⁾	TRG0 = 0	External trigger ⁽²⁾ Falling edge of a signal applied to \overline{ADTRG}
	TRG0 = 1	Hardware trigger ⁽²⁾ The timer B2 interrupt request of three-phase motor control timer functions (after the ICTB2 counter completes counting)

NOTES:

1. A/D0 starts the A/D conversion when the ADST bit is set to "1" (A/D conversion started) and a trigger is generated.
2. The A/D conversion is restarted if an external trigger or a hardware trigger is inserted during the A/D conversion. (The A/D conversion in process is aborted.)

17.2.4 DMAC Operating Mode

DMAC operating mode is available with all operating modes. When the A/D converter is in multi-port single sweep mode or multi-port repeat sweep mode 0, the DMAC operating mode must be used. When the DUS bit in the AD0CON3 register is set to "1" (DMAC operating mode enabled), all A/D conversion results are stored into the AD00 register. DMAC transfers data from the AD00 register to any memory space every time an A/D conversion is completed in each pin. 8-bit DMA transfer must be selected for 8-bit resolution and 16-bit DMA transfer for 10-bit resolution. Refer to **12. DMAC** for instructions.

17.2.5 Extended Analog Input Pins

In one-shot mode and repeat mode, the ANEX0 and ANEX1 pins can be used as analog input pins. The OPA1 and OPA0 bits in the AD0CON1 register select which pins to use as analog input pins. An A/D conversion result for the ANEX0 pin is stored into the AD00 register. The result for the ANEX1 pin is stored into the AD01 register, but is stored into the AD00 register when the DUS bit in the AD0CON3 register is set to "1" (DMAC operating mode enabled).

17.2.6 External Operating Amplifier (Op-Amp) Connection Mode

In external op-amp connection mode, multiple analog voltage can be amplified by one external op-amp using extended analog input pins ANEX0 and ANEX1.

When the OPA1 and OPA0 bits in the AD0CON1 register are set to "112" (external op-amp connection), voltage applied to the AN₀ to AN₇ pins are output from ANEX0. Amplify this output signal by an external op-amp and apply it to ANEX1.

Analog voltage applied to ANEX1 is converted to a digital code and the A/D conversion result is stored into the corresponding AD0_j register (j=0 to 7). A/D conversion rate varies depending on the response of the external op-amp. The ANEX0 pin cannot be connected to the ANEX1 pin directly.

Figure 17.7 shows an example of an external op-amp connection.

Table 17.10 Extended Analog Input Pin Settings

AD0CON1 Register		ANEX0 Function	ANEX1 Function
OPA1 Bit	OPA0 Bit		
0	0	Not used	Not used
0	1	P9 ₅ as an analog input	Not used
1	0	Not used	P9 ₆ as an analog input
1	1	Output to an external op-amp	Input from an external op-amp

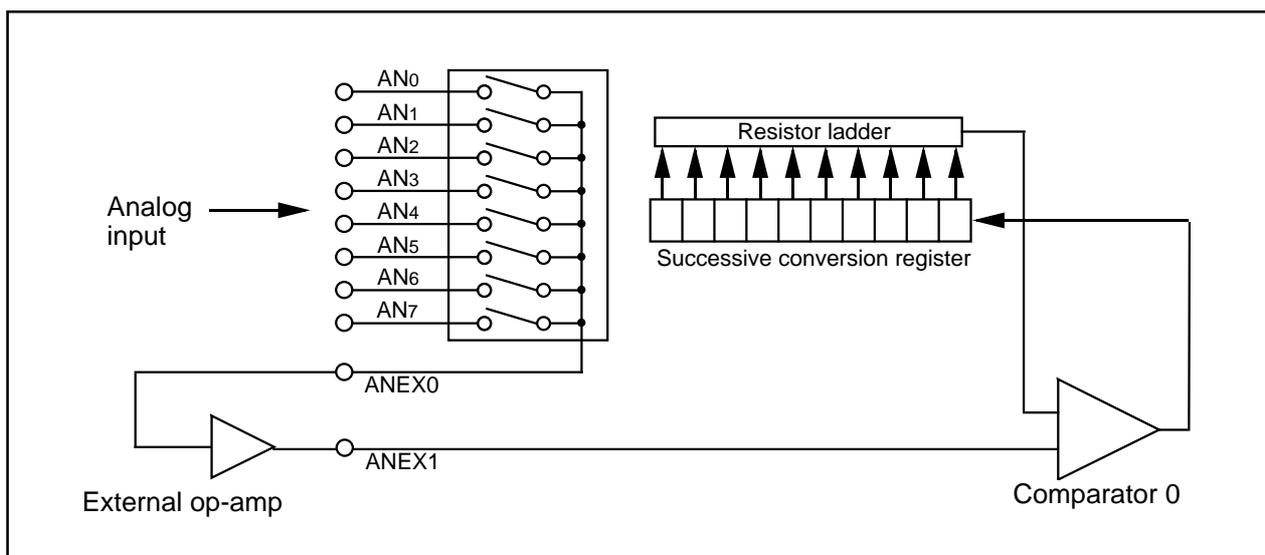

Figure 17.7 External Op-Amp Connection

17.2.7 Power Consumption Reducing Function

When the A/D converter is not used, the VCUT bit in the AD0CON1 register isolates the resistor ladder of the A/D converter from the reference voltage input pin (VREF). Power consumption is reduced by shutting off any current flow into the resistor ladder from the VREF pin.

When using the A/D converter, set the VCUT bit to "1" (VREF connection) before setting the ADST bit in the AD0CON0 register to "1" (A/D conversion started). Do not set the ADST bit and VCUT bit to "1" simultaneously, nor set the VCUT bit to "0" (no VREF connection) during the A/D conversion. The VCUT bit does not affect the VREF performance of the D/A converter.

17.2.8 Output Impedance of Sensor Equivalent Circuit under A/D Conversion

For perfect A/D converter performance, complete internal capacitor (C) charging, shown in Figure 17.8, for the specified period (T) as sampling time. Output Impedance of the sensor equivalent circuit (R₀) is determined by the following equations:

$$V_C = V_{IN} \left\{ 1 - e^{-\frac{1}{C(R_0 + R)} t} \right\}$$

$$\text{When } t = T, \quad V_C = V_{IN} - \frac{X}{Y} V_{IN} = V_{IN} \left(1 - \frac{X}{Y} \right)$$

$$e^{-\frac{1}{C(R_0 + R)} T} = \frac{X}{Y}$$

$$-\frac{1}{C(R_0 + R)} T = \ln \frac{X}{Y}$$

$$R_0 = -\frac{T}{C \cdot \ln \frac{X}{Y}} - R$$

where:

V_C = Voltage between pins

R = Internal resistance of the microcomputer

X = Precision (error) of the A/D converter

Y = Resolution of the A/D converter (1024 in 10-bit mode, and 256 in 8-bit mode)

Figure 17.8 shows analog input pin and external sensor equivalent circuit. The impedance (R₀) can be obtained if the voltage between pins (V_C) changes from 0 to V_{IN} - (0.1/1024) V_{IN} in the time (T), when the difference between V_{IN} and V_C becomes 0.1LSB.

(0.1/1024) means that A/D precision drop, due to insufficient capacitor charge, is held to 0.1LSB at time of A/D conversion in the 10-bit mode. Actual error, however, is the value of absolute precision added to 0.1LSB. When $\phi_{AD} = 10$ MHz, T = 0.3 μ s in the A/D conversion mode with the sample and hold function. Output impedance (R₀) for sufficiently charging capacitor (C) in the time (T) is determined by the following equation:

Using T = 0.3 μ s, R = 7.8 k Ω , C = 1.5 pF, X = 0.1, Y = 1024,

$$R_0 = -\frac{0.3 \times 10^{-6}}{1.5 \times 10^{-12} \cdot \ln \frac{0.1}{1024}} - 7.8 \times 10^3 = 13.9 \times 10^3$$

Thus, the allowable output impedance of the sensor equivalent circuit, making the precision (error) 0.1LSB or less, is approximately 13.9 k Ω maximum.

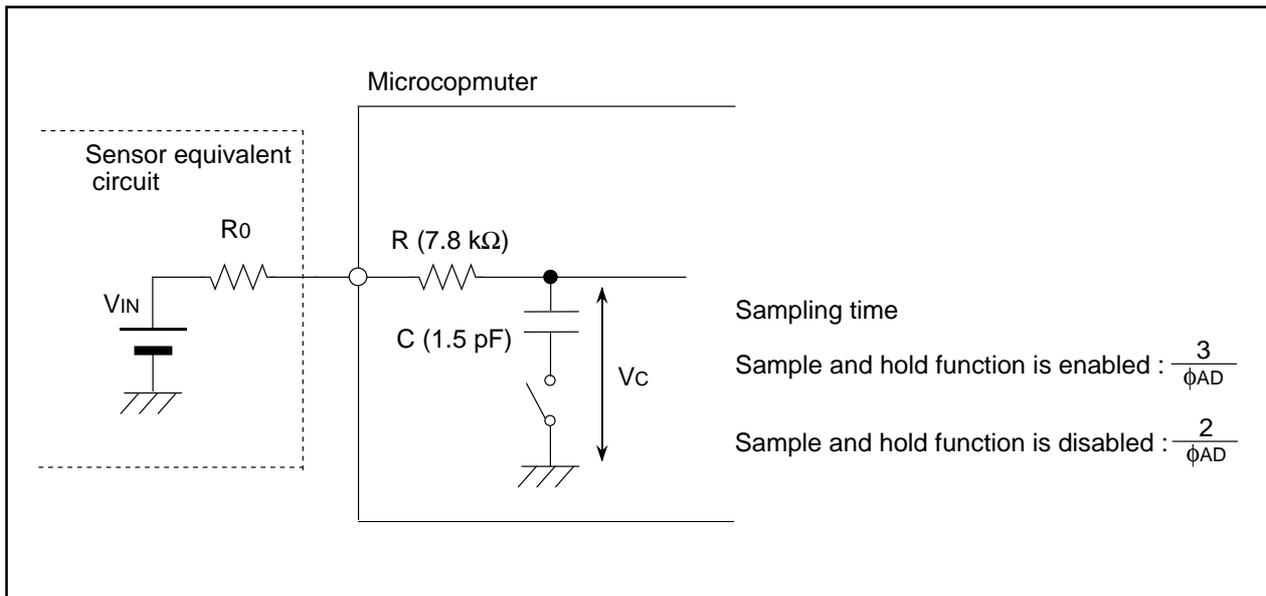

Figure 17.8 Analog Input Pin and External Sensor Equivalent Circuit

18. D/A Converter

The D/A converter consists of two separate 8-bit R-2R ladder D/A converters.

Digital code is converted to an analog voltage when a value is written to the corresponding DAi registers (i=0,1). The DAiE bit in the DACON register determines whether the D/A conversion result output is provided or not. Set the DAiE bit to "1" (output enabled) to disable a pull-up of a corresponding port.

Output analog voltage (V) is calculated from value n (n =decimal) set in the DAi register.

$$V = \frac{V_{REF} \times n}{256} \quad (n = 0 \text{ to } 255)$$

V_{REF} : reference voltage (not related to VCUT bit setting in the AD0CON1 register)

Table 18.1 lists specifications of the D/A converter. Table 18.2 lists the DA0 and DA1 pin settings. Figure 18.1 shows a block diagram of the D/A converter. Figure 18.2 shows the D/A control register. Figure 18.3 shows a D/A converter equivalent circuit.

When the D/A converter is not used, set the DAi register to "0016" and the DAiE bit to "0" (output disabled).

Table 18.1 D/A Converter Specifications

Item	Specification
D/A Conversion Method	R-2R
Resolution	8 bits
Analog Output Pin	2 channels

Table 18.2 Pin Settings

Port	Function	Setting		
		PD9 Register ⁽¹⁾	PS3 Register ⁽¹⁾	PSL3 Register
P93	DA0 output	PD9_3=0	PS3_3=0	PSL3_3=1
P94	DA1 output	PD9_4=0	PS3_4=0	PSL3_4=1

NOTE:

1. Set the PD9 and PS3 registers immediately after the PRC2 bit in the PRCR register is set to "1" (write enable). Do not generate an interrupt or a DMA transfer between the instruction to set the PRC2 bit to "1" and the instruction to set the PD9 and PS3 registers.

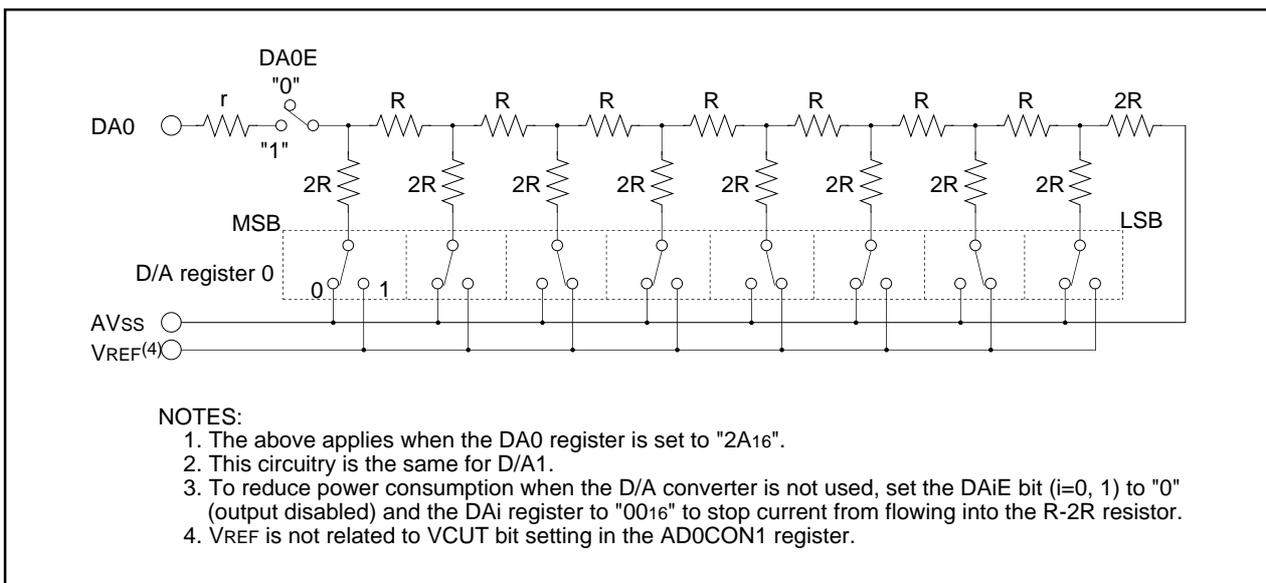

Figure 18.3 D/A Converter Equivalent Circuit

19. CRC Calculation

The CRC (Cyclic Redundancy Check) calculation detects an error in data blocks. A generator polynomial of CRC_CCITT ($X^{16} + X^{12} + X^5 + 1$) generates CRC code.

The CRC code is a 16-bit code generated for a block of data of desired length. This block of data is in 8-bit units. The CRC code is set in the CRCD register every time one-byte data is transferred to the CRCIN register after a default value is written to the CRCD register. CRC code generation for one-byte data is completed in two cycles.

Figure 19.1 shows a block diagram of a CRC circuit. Figure 19.2 shows CRC-associated registers. Figure 19.3 shows an example of the CRC calculation.

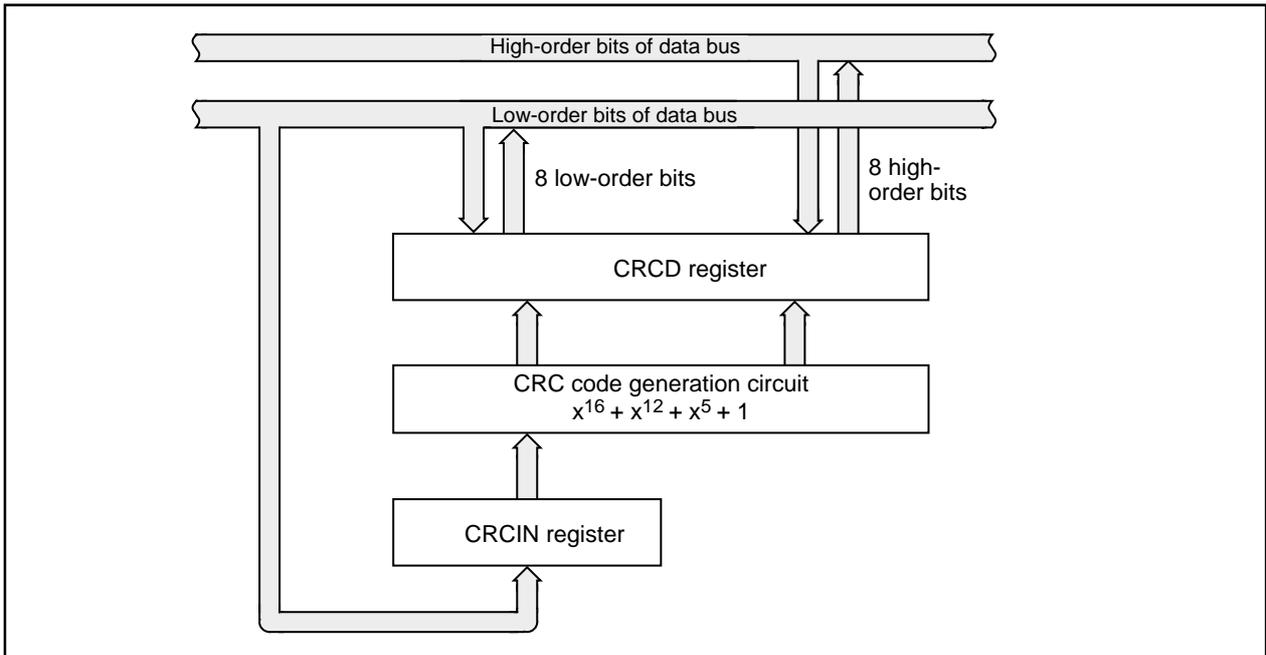

Figure 19.1 CRC Calculation Block Diagram

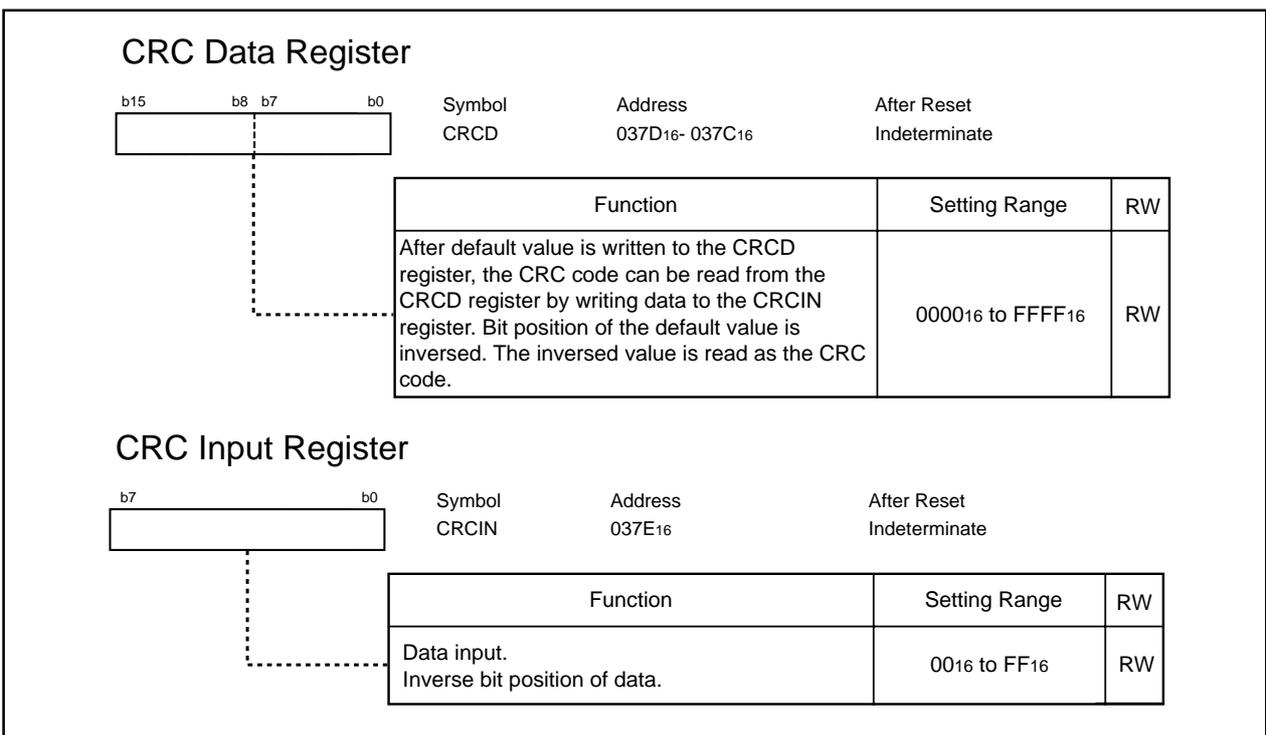

Figure 19.2 CRCD Register and CRCIN Register

CRC Calculation and Setup Procedure to Generate CRC Code for "80C416"

○ CRC Calculation for M32C

CRC Code : a remainder of a division, $\frac{\text{value of the CRCIN register with inversed bit position}}{\text{generator polynomial}}$

Generator Polynomial : $X^{16} + X^{12} + X^5 + 1$ (1 0001 0000 0010 0001₂)

○ Setting Steps

(1) Inverse a bit position of "80C416" per byte by program

"8016" → "0116", "C416" → "2316"

(2) Set "000016" (default value) →  CRCD register

(3) Set "0116" →  CRCIN register
 Bit position of the CRC code for "8016" (918816) is inversed to "118916", which is stored into the CRCD register in 3rd cycle.

 CRCD register

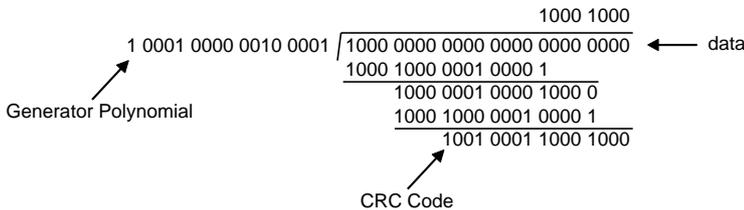

(4) Set "2316" →  CRCIN register
 Bit position of the CRC code for "80C416" (825016) is inversed to "0A4116", which is stored into the CRCD register in 3rd cycle.

 CRCD register

○ Details of CRC Calculation

As shown in (3) above, bit position of "0116" (00000001₂) written to the CRCIN register is inversed and becomes "10000002".

Add "1000 0000 0000 0000 0000 0000₂", as "10000002" plus 16 digits, to "000016" as the default value of the CRCD register to perform the modulo-2 division.

Modulo-2 Arithmetic is calculated on the law below.

- 0 + 0 = 0
- 0 + 1 = 1
- 1 + 0 = 1
- 1 + 1 = 0
- 1 = 1

"0001 0001 1000 1001₂ (118916)", the remainder "1001 0001 1000 1000₂ (918816)" with inversed bit position, can be read from the CRCD register.

When going on to (4) above, "2316 (00100011₂)" written in the CRCIN register is inversed and becomes "11000100₂".

Add "1100 0100 0000 0000 0000 0000₂", as "11000100₂" plus 16 digits, to "1001 0001 1000 1000₂" as a remainder of (3) left in the CRCD register to perform the modulo-2 division.

"0000 1010 0100 0001₂ (0A4116)", the remainder with inversed bit position, can be read from CRCD register.

Figure 19.3 CRC Calculation

20. X/Y Conversion

The X/Y conversion rotates a 16 x 16 matrix data by 90 degrees and inverses high-order bits and low-order bits of a 16-bit data. Figure 20.1 shows the XYC register.

The 16-bit XiR register ($i=0$ to 15) and 16-bit YjR register ($j=0$ to 15) are allocated to the same address. The XiR register is a write-only register, while the YjR register is a read-only register. Access the XiR and YjR registers from an even address in 16-bit units. Performance cannot be guaranteed if the XiR and YiR registers are accessed in 8-bit units.

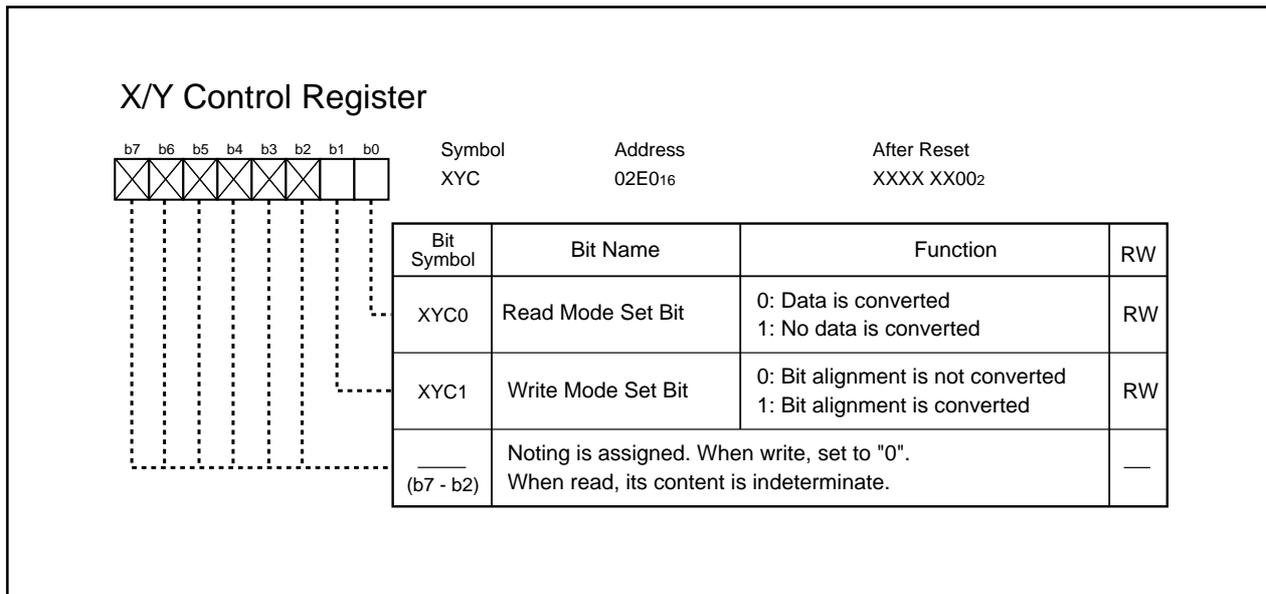

Figure 20.1 XYC Register

The XYC0 bit in the XYC register determines how to read the YjR register.

By reading the YjR register when the XYC0 bit is set to "0" (data conversion), bit j in the X0R to X15R registers can be read simultaneously.

For example, bit 0 in the X0R register can be read if reading bit 0 in the Y0R register, bit 0 in the X1R register if reading bit 1 in the Y0R register..., bit 0 in the X14R register if reading bit 14 in the Y0R register and bit 0 in the X15R register if reading bit 15 in the Y0R register.

Figure 20.2 shows the conversion table when the XYC0 bit is set to "0". Figure 20.3 shows an example of the X/Y conversion.

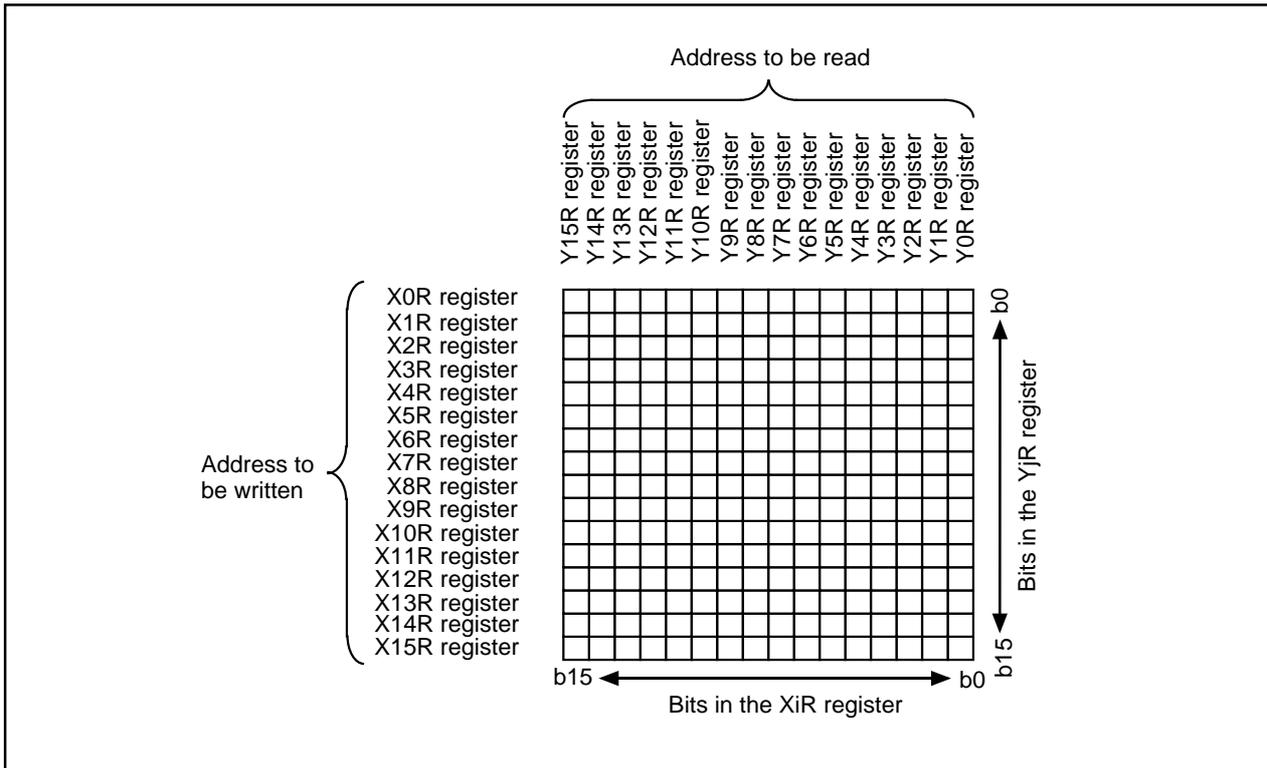

Figure 20.2 Conversion Table when Setting the XYC0 Bit to "0"

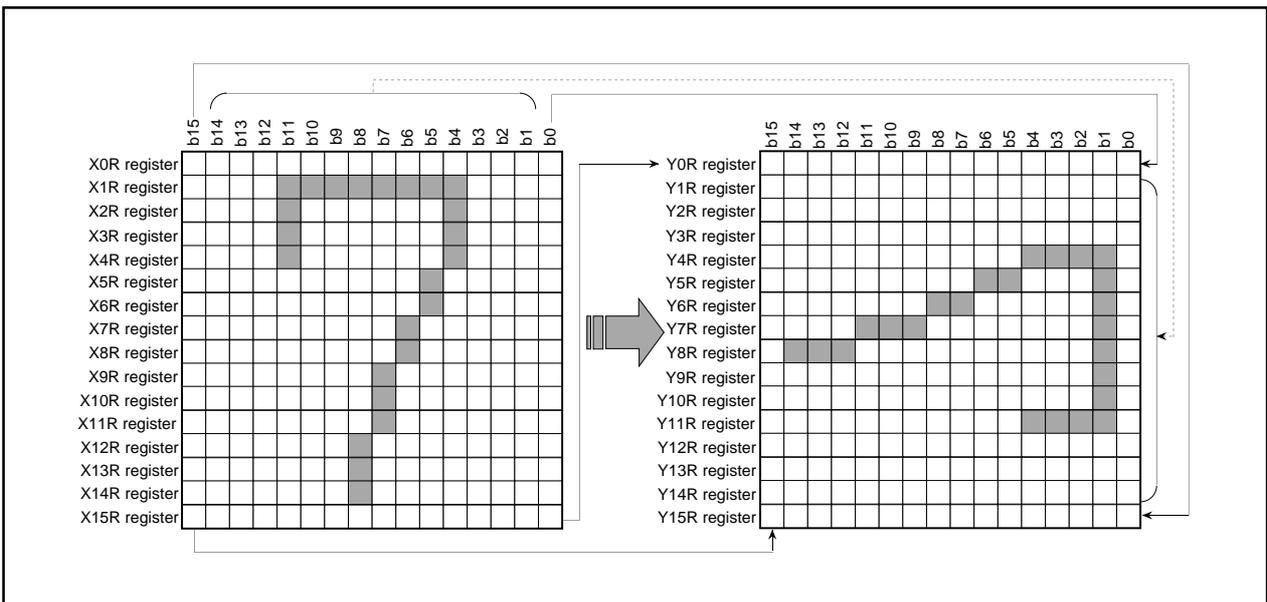

Figure 20.3 X/Y Conversion

By reading the YjR register when the XYC0 bit in the XYC register is set to "1" (no data conversion), the value written to the XiR register can be read directly. Figure 20.4 shows the conversion table when the XYC0 bit is set to "1."

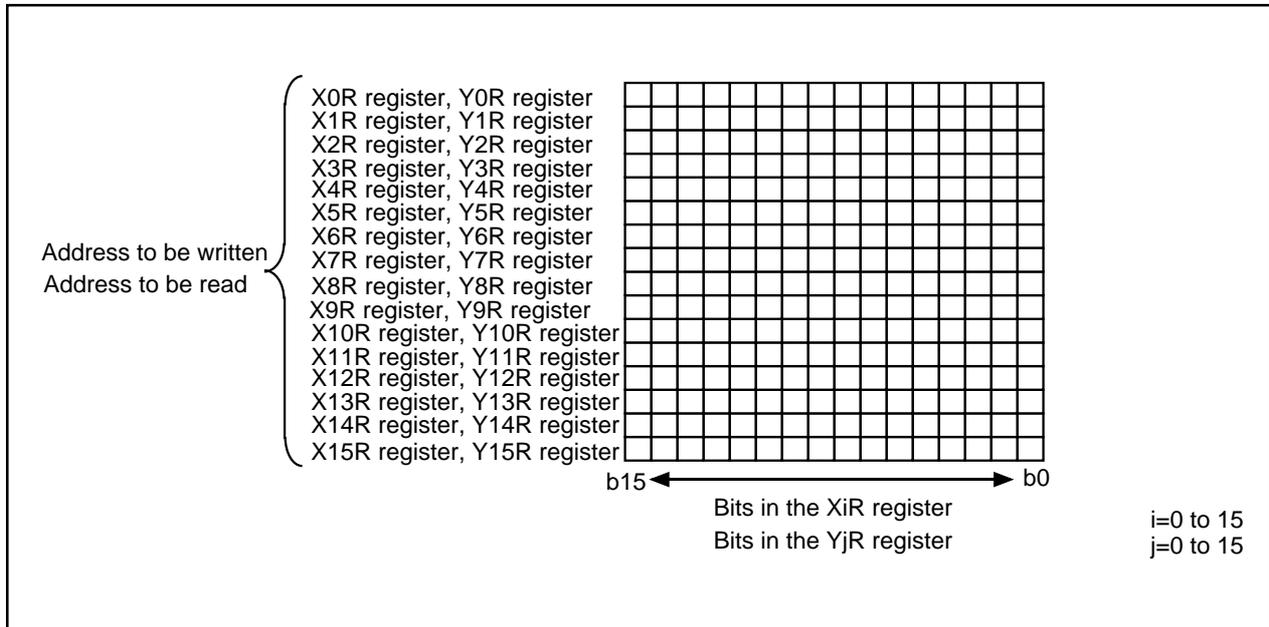

Figure 20.4 Conversion Table when Setting the XYC0 Bit to "1"

The XYC1 bit in the XYC register selects bit alignment of the value in the XiR register.

By writing to the XiR register while the XYC1 bit is set to "0" (no bit alignment conversion), bit alignment is written as is. By writing to the XiR register while the XYC1 bit is set to "1" (bit sequence replaced), bit alignment is written inversed.

Figure 20.5 shows the conversion table when the XYC1 bit is set to "1".

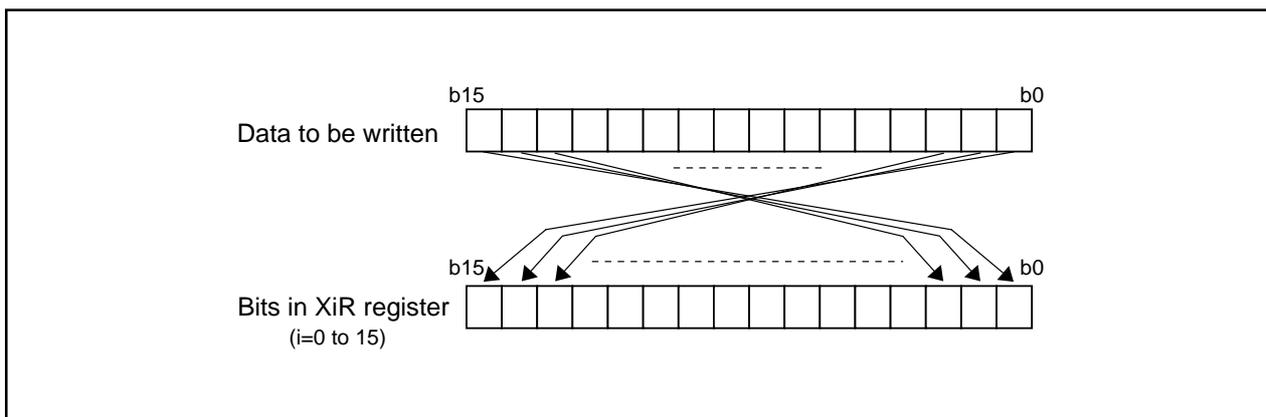

Figure 20.5 Conversion Table when Setting the XYC1 Bit to "1"

21. Intelligent I/O

The intelligent I/O is a multifunctional I/O port for clock synchronous serial I/O and HDLC data processing.

The intelligent I/O has two sets of two 8-bit shift registers for communications.

Table 21.1 lists functions and channels of the intelligent I/O.

Table 21.1 Intelligent I/O Functions and Channels

Function	Description	
Communication	Communication unit 0	Communication unit 1
Clock Synchronous Serial I/O Mode	Available	Available
HDLC Data Processing Mode	Available	

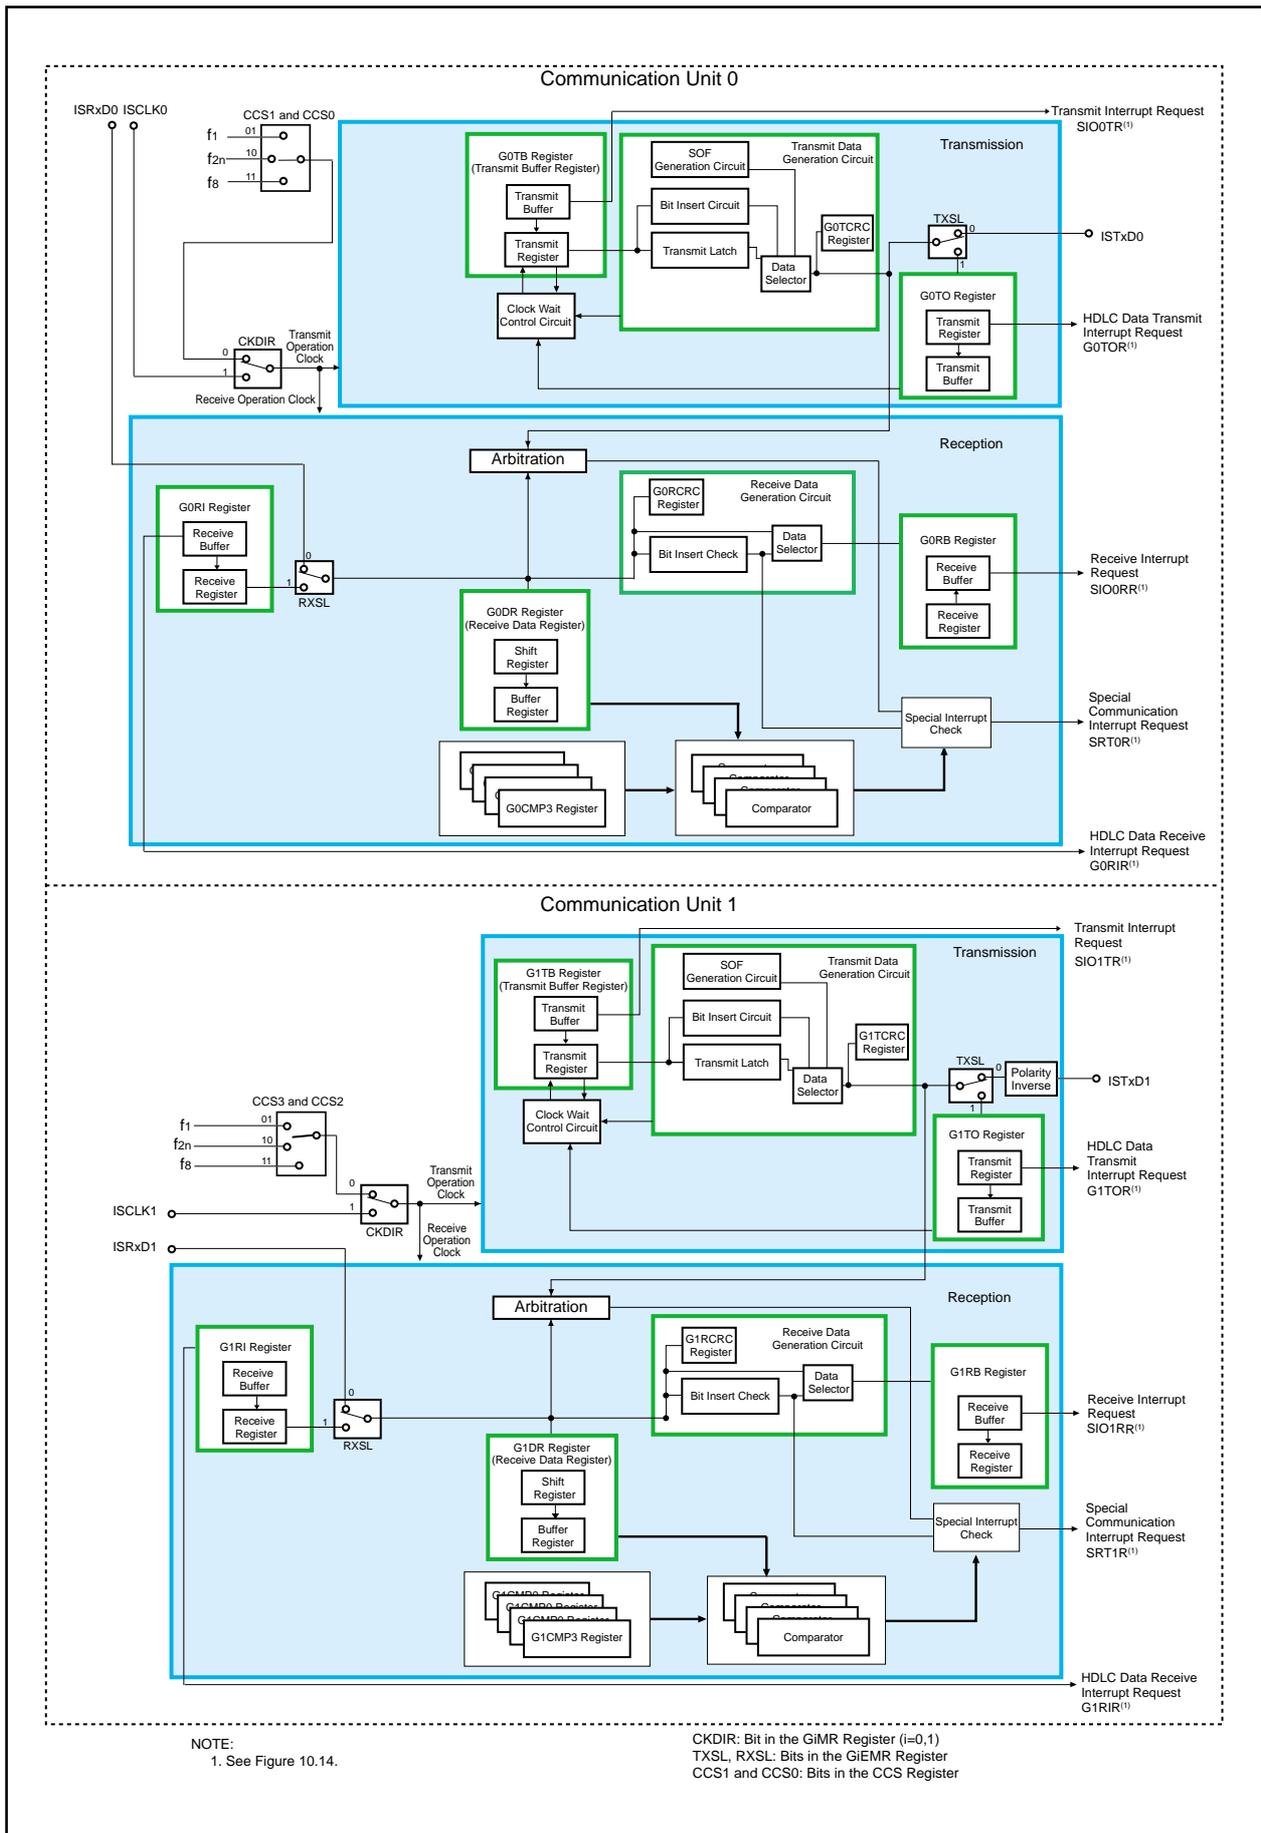

Figure 21.1 Intelligent I/O Communication Unit Block Diagram

21.1 Communication Unit 0 and 1 Communication Function

In the intelligent I/O communication units, 8-bit clock synchronous serial I/O or HDLC data processing is available.

Figures 21.2 to 21.11 show registers associated with the communication function.

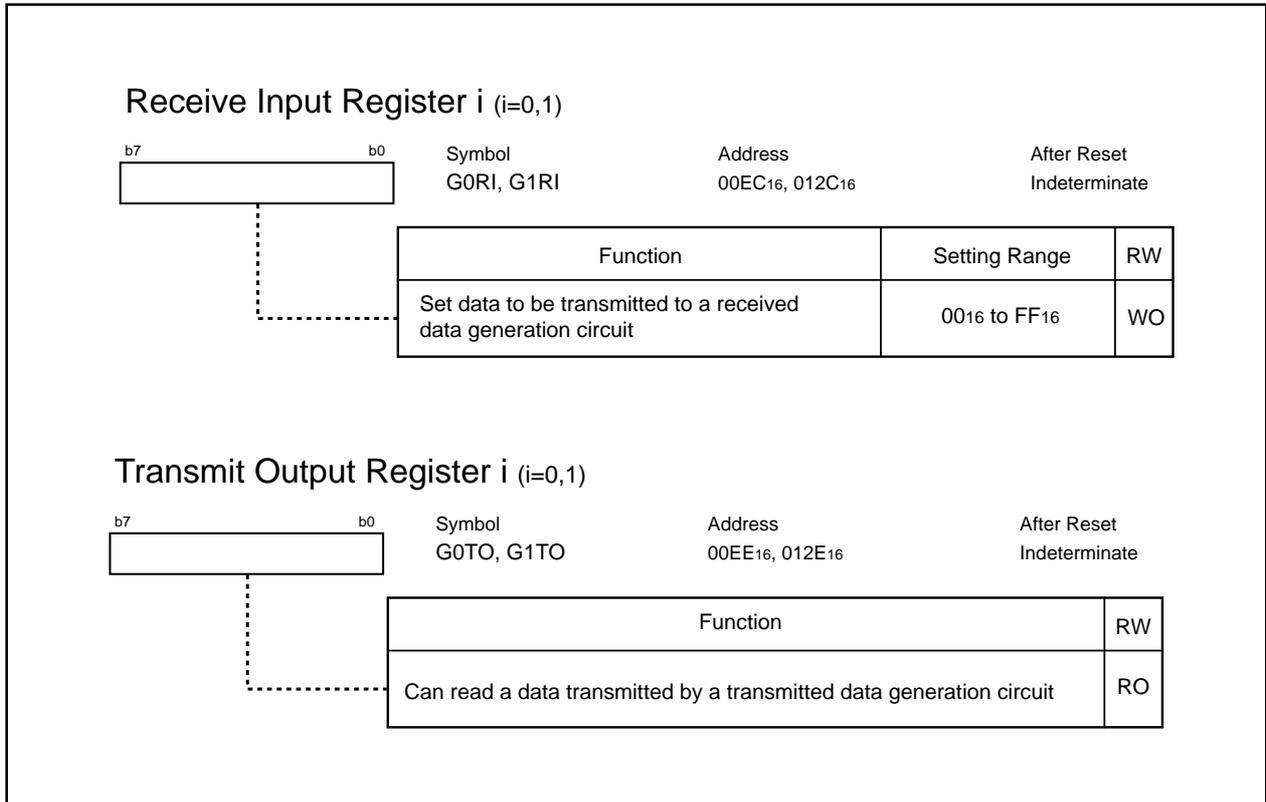

Figure 21.2 G0RI and G1RI Registers, G0TO and G1TO Registers

				G0TCRC, G1TCRC	00FB ₁₆ -00FA ₁₆ , 013B ₁₆ -013A ₁₆	0000 ₁₆
				Function	RW	
				Result of the transmit CRC calculation ^(1, 2)	RO	

NOTES:

- The calculated result is reset by setting the TE bit in the GiCR register to "0" (transmit disabled).
The CRCV bit in the GiEMR register selects a default value.
- Transmit CRC calculation is performed with each bit of data transmitted while the TCRCE bit in the GiETC register is set to "1" (used).

Receive CRC Code Register i (i=0,1)

b15	b8	b7	b0	Symbol	Address	After Reset
				G0RCRC, G1RCRC	00F9 ₁₆ -00F8 ₁₆ , 0139 ₁₆ -0138 ₁₆	Indeterminate
				Function	RW	
				Result of the receive CRC calculation ^(1, 2, 3)	RO	

NOTES:

- The calculated result is reset by setting the RCRCE bit in the GiERC register to "0" (not used).
If the ACRC bit in the GiEMR register is set to "1" (reset), the result is reset by matching data in the GiCMPj register (j=0 to 3) with the received data.
- The result is reset to the default value selected by the CRCV bit in the GiEMR register before reception starts.
- Receive CRC calculation is performed with every bit of data received while the RCRCE bit in the GiERC register is set to "1" (used).

21.1.1 Clock Synchronous Serial I/O Mode (Communication Units 0 and 1)

In clock synchronous serial I/O mode, data is transmitted and received with the transfer clock. f_8 or f_{2n} can be selected as the transfer clock.

Table 21.2 lists specifications of clock synchronous serial I/O mode for the communication units 0 and 1. Tables 21.3 and 21.4 list clock settings. Table 21.5 lists register settings. Tables 21.6 and 21.7 list pin settings. Figure 21.12 shows an example of transmit and receive operation.

Table 21.2 Clock Synchronous Serial I/O Mode Specifications (Communication Units 0 and 1)

Item	Specification
Transfer Data Format	Transfer data: 8 bits long
Transfer Clock ⁽¹⁾	See Tables 21.3 and 21.4
Transmit Start Condition	Set registers associated with the waveform generating function, the GiMR and GiERC registers ($i=0,1$). Then, set as is written below after at least one transfer clock cycle. <ul style="list-style-type: none"> • Set the TE bit in the GiCR register to "1" (transmit enabled) • Set the TI bit in the GiCR register to "0" (data in the GiTB register)
Receive Start Condition	Set registers associated with the waveform generating function, the GiMR and GiERC registers. Then, set as is written below after at least one transfer clock cycle. <ul style="list-style-type: none"> • Set the RE bit in the GiCR register to "1" (receive enabled) • Set the TE bit to "1" (transmit enabled) • Set the TI bit to "0" (data in the GiTB register)
Interrupt Request	<ul style="list-style-type: none"> • While transmitting, one of the following conditions can be selected to set the SIOiTR bit to "1" (interrupt requested) (See Figure 10.14): <ul style="list-style-type: none"> – The IRS bit in the GiMR register is set to "0" (no data in the GiTB register) and data is transferred to the transmit register from the GiTB register – The IRS bit is set to "1" (transmission completed) and data transfer from the transmit register is completed • While receiving, the following condition can be selected to set SIOiRR bit is set to "1" (data reception is completed): <ul style="list-style-type: none"> – Data is transferred from the receive register to the GiRB register (See Figure 10.14)
Error Detection	Overrun error ⁽²⁾ This error occurs, when the next data reception is started and the 8th bit of the next data is received before reading the GiRB register
Selectable Function	<ul style="list-style-type: none"> • LSB first or MSB first Select either bit 0 or bit 7 to transmit or receive data

NOTES:

1. In clock synchronous serial I/O mode, set the RSHTTE bit in the GiERC register ($i=0, 1$) to "1" (receive shift operation enabled).
2. When an overrun error occurs, the GiRB register is indeterminate.

The ISTxDi pin outputs a high-level ("H") signal between selecting operating mode and starting transfer.

21.1.2 HDLC Data Processing Mode (Communication Units 0 and 1)

In HDLC data processing mode, bit stuffing, flag detection, abort detection and CRC calculation are available for HDLC control. f1, f8 or f2n can be selected as the transfer clock. No pin is used.

To convert data, data to be transmitted is written to the GiTB register (i=0,1) and the data conversion result is restored after data conversion. If any data are in the GiTO register after data conversion, the conversion is terminated. If no data is in the GiTO register, bit stuffing processing is executed regardless of no data available in the transmit output buffer. A CRC value is calculated every time one bit is converted. If no data is in the GiRI register, received data conversion is terminated.

Table 21.8 list specifications of the HDLC data processing mode. Tables 21.9 and 21.10 list clock settings. Table 21.11 lists register settings.

Table 21.8 HDLC Processing Mode Specifications (Communication Units 0 and 1)

Item	Specification
Input Data Format	8-bit data fixed, bit alignment is optional
Output Data Format	8-bit data fixed
Transfer Clock	See Tables 21.9 and 21.10
I/O Method	<ul style="list-style-type: none"> • During transmit data processing, value set in the GiTB register is converted in HDLC data processing mode and transferred to the GiTO register. • During received data processing, value set in the GiRI register is converted in HDLC data processing mode and transferred to the GiRB register. The value in the GiRI register is also transferred to the GiTB register (received data register).
Bit Stuffing	During transmit data processing, "0" following five continuous "1" is inserted. During received data processing, "0" following five continuous "1" is deleted.
Flag Detection	Write the flag data "7E16" to the GiCMPj register (j=0 to 3) to use the special communication interrupt (the SRTiR bit in the IIO4IR register)
Abort Detection	Write the masked data "0116" to the GiMSKj register
CRC	<p>The CRC1 and CRC0 bits are set to "112" ($X^{16}+X^{12}+X^5+1$).</p> <p>The CRCV bit is set to "1" (set to "FFFF16").</p> <ul style="list-style-type: none"> • During transmit data processing, CRC calculation result is stored into the GiTCRC register. The TCRCE bit in the GiETC register is set to "1" (transmit CRC used). The CRC calculation result is reset when the TE bit in the GiCR register is set to "0" (transmit disabled). • During received data processing, CRC calculation result is stored into the GiRCRC register. The RCRCE bit in the GiERC register is set to "1" (receive CRC used). The CRC calculation result is reset by comparing the flag data "7E16" and matching the result with the value in the GiCMP3 register. The ACRC bit in the GiEMR register is set to "1" (CRC reset).
Data Processing Start Condition	<p>The following conditions are required to start transmit data processing:</p> <ul style="list-style-type: none"> • The TE bit in the GiCR register is set to "1" (transmit enabled) • Data is written to the GiTB register <p>The following conditions are required to start receive data processing:</p> <ul style="list-style-type: none"> • The RE bit in the GiCR register is set to "1" (receive enabled) • Data is written to the GiRI register

Table 21.8 HDLC Processing Mode Specifications (Continued)

Item	Specification
Interrupt Request ⁽¹⁾	<p>During transmit data processing,</p> <ul style="list-style-type: none"> • One of the following conditions can be selected to set the GiTOR bit in the interrupt request register to "1" (interrupt request) (see Figure 10.14). <ul style="list-style-type: none"> – When the IRS bit in the GiMR register is set to "0" (no data in the GiTB register) and data is transferred from the GiTB register to the transmit register (transmit start). – When the IRS bit is set to "1" (transmission completed) and data transfer from the transmit register to the GiTO register is completed. • When data, which is already converted to HDLC data, is transferred from the receive register of the GiTO register to the transmit buffer, the GiTOR bit is set to "1" <p>During received data processing,</p> <ul style="list-style-type: none"> • When data is transferred from the GiRI register to the GiRB register (reception completed), the GiRIR bit is set to "1" (See Figure 10.14). • When received data is transferred from the receive buffer of the GiRI register to the receive register, the GiRIR bit is set to "1". • When the GiTB register is compared to the GiCMPj register (j=0 to 3), the SRTiR bit is set to "1".

NOTE:

1. See **Figure 10.14** for details on the GiTOR bit, GiRIR bit and SRTiR bit.

GiETC	TCRCE	Select whether transmit CRC is used or not
	TBSF1, TBSF0	Transmit bit stuffing
GiERC	CMP2E to CMP0E	Select whether received data is compared or not
	CMP3E	Set to "1"
	RCRCE	Select whether receive CRC is used or not
	RSHTE	Set to "1" to use it in the receiver
	RBSF1, RBSF0	Receive bit stuffing
GiIRF	BSERR	Set to "0"
	IRF3 to IRF0	Select what causes an interrupt to be generated
GiCMP0, GiCMP1	7 to 0	Write "FE16" to abort processing
GiCMP2	7 to 0	Data to be compared
GiCMP3	7 to 0	Write "7E16"
GiMSK0, GiMSK1	7 to 0	Write "0116" to abort processing
GiTCRC	15 to 0	Transmit CRC calculation result can be read
GiRCRC	15 to 0	Receive CRC calculation result can be read
GiTO	7 to 0	Data, which is output from a transmit data generation circuit, can be read
GiRI	7 to 0	Set data input to a receive data generation circuit
GiRB	7 to 0	Received data is stored
GiTB	7 to 0	For transmission: write data to be transmitted For reception: received data for comparison is stored
CCS	CCS1, CCS0	Select the HDLC processing clock
	CCS3, CCS2	Select the HDLC processing clock

i=0, 1

22. Programmable I/O Ports

87 programmable I/O ports from ports P0 to P10 (excluding P85) are available. The direction registers determine each port status, input or output. The pull-up control registers determine whether the ports, divided into groups of four ports, are pulled up or not. P85 is an input port and no pull-up for this port is allowed. The P8_5 bit in the P8 register indicates an $\overline{\text{NMI}}$ input level since P85 shares pins with $\overline{\text{NMI}}$.

Figures 22.1 to 22.4 show programmable I/O port configurations.

Each pin functions as the programmable I/O port, an I/O pin for internal peripheral functions or the bus control pin.

To use the pins as input or output pins for internal peripheral functions, refer to the explanations for each function. Refer to **7. Bus** when used as the bus control pin.

The registers associated with the programmable I/O ports are as follows.

22.1 Port Pi Direction Register (PDi Register, i=0 to 10)

Figure 22.5 shows the PDi register.

The PDi register selects input or output status of a programmable I/O port. Each bit in the PDi register corresponds to a port.

In memory expansion and microprocessor mode, the PDi register cannot control pins being used as bus control pins (A0 to A22, $\overline{\text{A23}}$, D0 to D15, $\overline{\text{CS0}}$ to $\overline{\text{CS3}}$, $\overline{\text{WRL/WR}}$, $\overline{\text{WRH/BHE}}$, $\overline{\text{RD}}$, BCLK/ALE/CLKOUT, $\overline{\text{HLDA/ALE}}$, HOLD, ALE and RDY). No bit controlling P85 is provided in the direction registers.

22.2 Port Pi Register (Pi Register, i=0 to 10)

Figure 22.6 shows the Pi register.

The Pi register writes and reads data to communicate with external devices. The Pi register consists of a port latch to hold output data and a circuit to read pin states. Each bit in the Pi register corresponds to a port. In memory expansion and microprocessor mode, the Pi register cannot control pins being used as bus control pins (A0 to A22, $\overline{\text{A23}}$, D0 to D15, $\overline{\text{CS0}}$ to $\overline{\text{CS3}}$, $\overline{\text{WRL/WR}}$, $\overline{\text{WRH/BHE}}$, $\overline{\text{RD}}$, BCLK/ALE/CLKOUT, $\overline{\text{HLDA/ALE}}$, HOLD, ALE and RDY).

22.3 Function Select Register Aj (PSj Register) (j=0 to 3)

Figures 22.7 and 22.8 show the PSj registers.

The PSj register selects either I/O port or peripheral function output if an I/O port shares pins with a peripheral function output (excluding DA0 and DA1.)

When multiple peripheral function outputs are assigned to a pin, set the PSL0 to PSL3, PSC, PSC3, and PSD1 registers to select which function is used.

Tables 22.3 to 22.10 list peripheral function output control settings for each pin.

22.4 Function Select Register B0 to B3 (PSL0 to PSL3 Registers)

Figures 22.9 and 22.10 show the PSL0 to PSL3 registers.

When multiple peripheral function outputs are assigned to a pin, the PSL0 to PSL3 registers select which peripheral function output is used.

Refer to **22.10 Analog Input and Other Peripheral Function Input** for the PSL3_6 to PSL3_3 bits in the PSL3 register.

22.5 Function Select Register C (PSC and PSC3 Registers)

Figures 22.11 and 22.12 show the PSC and PSC3 registers.

When multiple peripheral function outputs are assigned to a pin, the PSC and PSC3 registers select which peripheral function output is used.

Refer to **22.10 Analog Input and Other Peripheral Function Input** for the PSC_7 bit in the PSC register.

22.6 Function Select Register D (PSD1 Register)

Figure 22.12 shows the PSD1 register.

When multiple peripheral function outputs are assigned to a pin, the PSD1 register selects which peripheral function output is used.

22.7 Pull-up Control Register 0 to 3 (PUR0 to PUR3 Registers)

Figures 22.13 and 22.14 show the PUR0 to PUR3 registers.

The PUR0 to PUR3 registers select whether the ports, divided into groups of four ports, are pulled up or not. Ports with bits in the PUR0 to PUR3 registers set to "1" (pull-up) and the direction registers set to "0" (input mode) are pulled up.

Set bits in the PUR0 and PUR1 registers in ports P0 to P5, running as bus, to "0" (no pull-up) in memory expansion mode and microprocessor mode. Ports P0, P1 and P40 to P43 can be pulled up when they are used as input ports in memory expansion mode and microprocessor mode.

22.8 Port Control Register (PCR Register)

Figure 22.14 shows the PCR register.

The PCR register selects either CMOS output or N-channel open drain output as port P1 output format. If the PCR0 bit is set to "1", N-channel open drain output is selected because the P-channel in the CMOS port is turned off. This is, however, not a perfect open drain. Therefore, the absolute maximum rating of the input voltage is between -0.3V and $V_{CC2} + 0.3V$.

If P1 is used as a port for data bus in memory expansion mode and microprocessor mode, set the PCR0 bit to "0". If P1 is used as a port in memory expansion mode and microprocessor mode, the PCR0 bit determines the output format.

22.9 Analog Input and Other Peripheral Function Input

The PSL3_6 to PSL3_3 bits in the PSL3 register and the PSC_7 bit in the PSC register each separate analog I/O ports from other peripheral functions. Setting the corresponding bit to "1" (analog I/O) to use the analog I/O port (DA0, DA1, ANEX0, ANEX1, AN4 to AN7) prevents an intermediate potential from being impressed to other peripheral functions. The impressed intermediate potential may cause increase in power consumption.

Set the corresponding bit to "0" (except analog I/O) when analog I/O is not used. All peripheral function inputs except the analog I/O port are available when the corresponding bit is set to "0". These inputs are indeterminate when the bit is set to "1". When the PSC_7 bit is set to "1", key input interrupt request remains unchanged regardless of $\overline{KI0}$ to $\overline{KI3}$ pin input level change.

PDi_7	Port Pi7 Direction Bit	0: Input mode (Functions as input port) 1: Output mode (Functions as output port)	RW

NOTES:

- Set the PD9 register immediately after the PRC2 bit in the PRCR register is set to "1" (write enabled). Do not generate an interrupt or a DMA transfer between the instruction to set the PRC2 bit to "1" and the instruction to set the PD9 register.
- In memory expansion mode and microprocessor mode, the PDi register cannot control pins being used as bus control pins (A0 to A22, $\overline{A23}$, D0 to D15, $\overline{CS0}$ to $\overline{CS3}$, $\overline{WRL}/\overline{WR}$, $\overline{WRH}/\overline{BHE}$, $\overline{BCLK}/\overline{ALE}/\overline{CLKOUT}$, \overline{RD} , $\overline{HLDA}/\overline{ALE}$, \overline{HOLD} , \overline{ALE} and \overline{RDY}).
- Nothing is assigned in the PD8_5 bit in the PD8 register. If write, set these bits to "0". When read, their contents are indeterminate.

Pull-Up Control Register 0⁽¹⁾

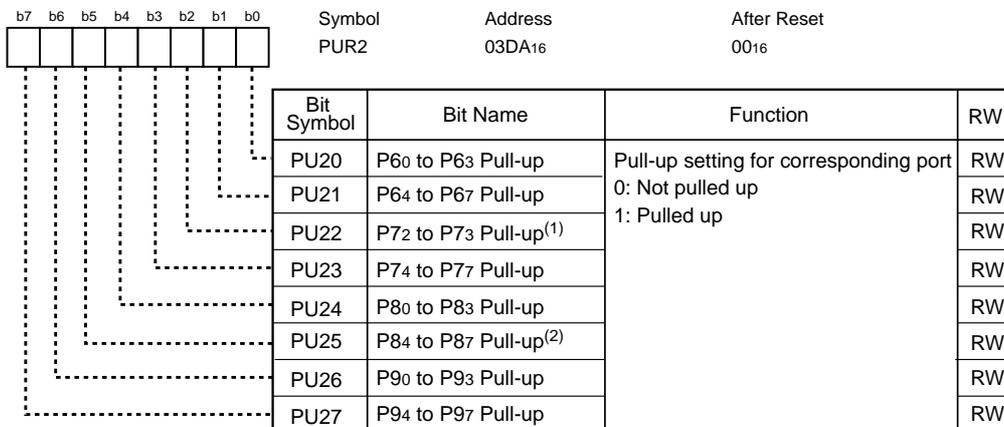

NOTE:
1. Set each bit in the PUR0 register to "0" when ports P0 to P5 become bus control pins in memory expansion mode and microprocessor mode. When using the ports as I/O ports, pull-up or no pull-up setting can be selected.

Pull-Up Control Register 1⁽¹⁾

NOTES:
1. Set each bit in the PUR1 register to "0" when ports P0 to P5 become bus control pins in memory expansion mode and microprocessor mode. When using the ports as I/O ports, pull-up or no pull-up setting can be selected.

Pull-Up Control Register 2

NOTES:
1. P7₀ and P7₁ cannot be pulled up.
2. P8₅ cannot be pulled up.

Figure 22.13 PUR0 Register, PUR1 Register and PUR2 Register

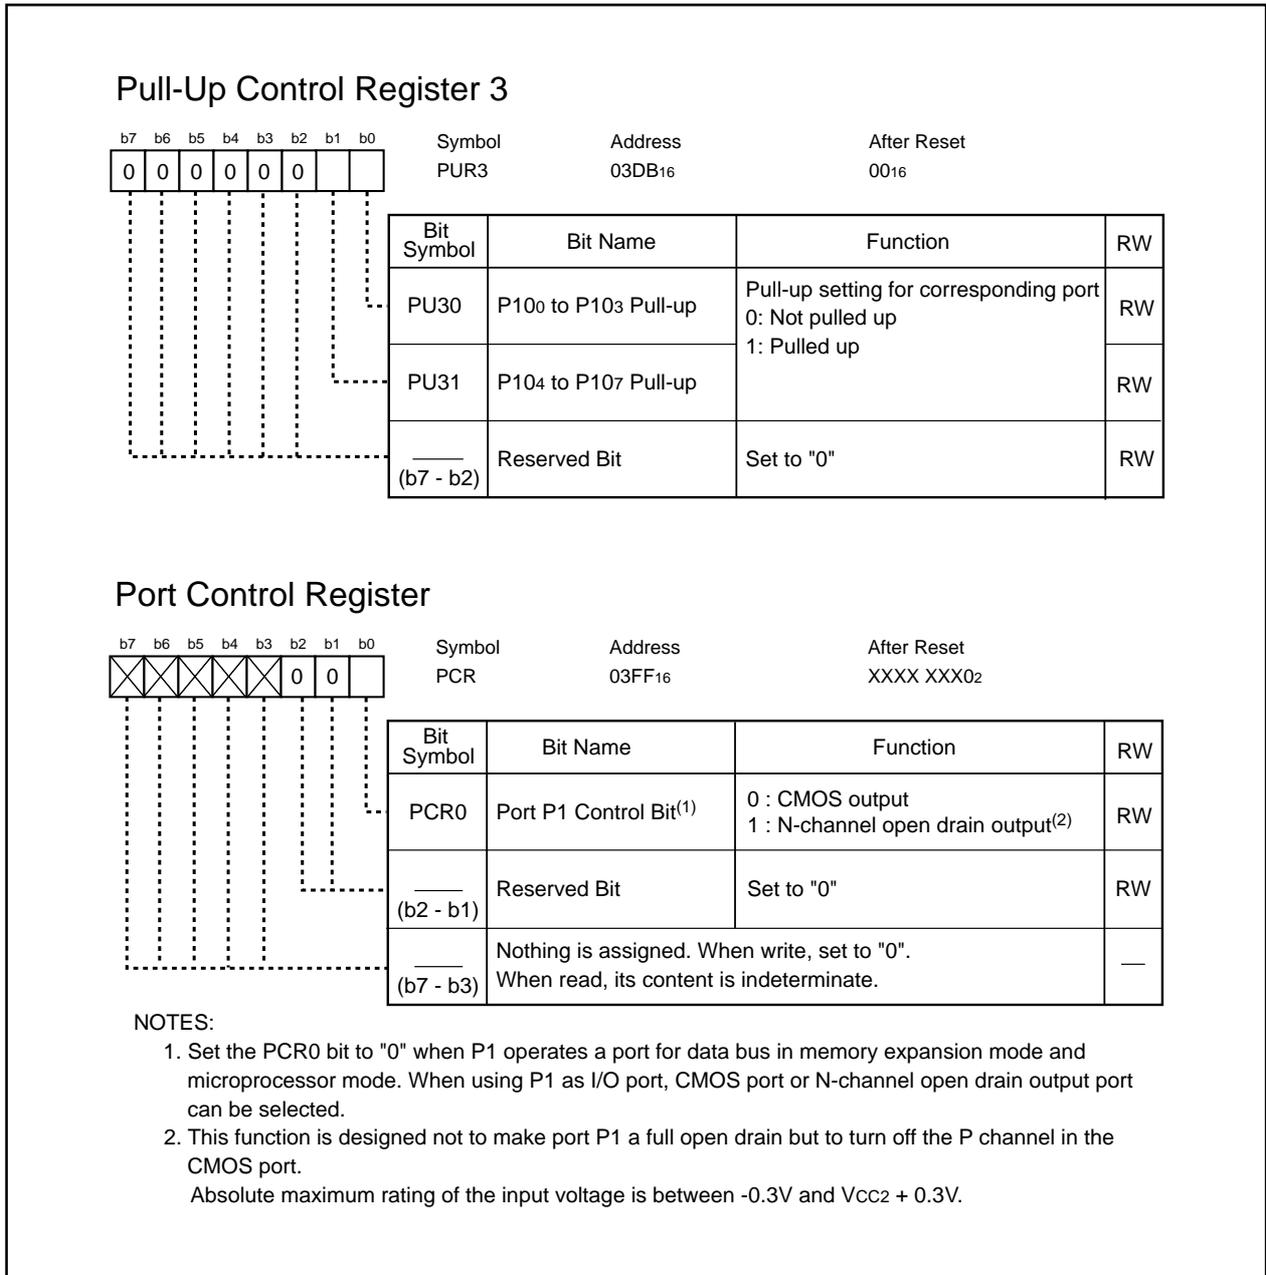

Figure 22.14 PUR3 Register and PCR Register

Table 22.1 Unassigned Pin Settings in Single-Chip Mode

Pin Name	Setting
P0 to P10 (excluding P85) ^(1,2,3)	Enter input mode and connect each pin to VSS via a resistor (pull-down); or enter output mode and leave pins open
XOUT ⁽⁴⁾	Leave pin open
NMI(P85)	Connect pin to VCC1 via a resistor (pull-up)
AVCC	Connect pin to VCC1
AVSS, VREF, BYTE	Connect pins to VSS

NOTES:

1. If the port enters output mode and is left open, it is in input mode before output mode is entered by program after reset. While the port is in input mode, voltage level on the pins is indeterminate and power consumption may increase.
Direction register settings may be changed by noise or failure caused by noise. Configure direction register settings regularly to increase the reliability of the program.
2. Use the shortest possible wiring to connect the microcomputer pins to unassigned pins (within 2 cm).
3. P70 and P71 must output low-level ("L") signals if they are in output mode. They are ports N-channel open drain outputs.
4. When the external clock is applied to the XIN pin, set the pin as written above.

Table 22.2 Unassigned Pin Setting in Memory Expansion Mode and Microprocessor Mode

Pin Name	Setting
P6 to P10 (excluding P85) ^(1,2,3)	Enter input mode and connect each pin to VSS via a resistor (pull-down); or enter output mode and leave pins open
BHE, ALE, HLDA, XOUT ⁽⁵⁾ , BCLK	Leave pin open
NMI(P85)	Connect pin to VCC1 via a resistor (pull-up)
RDY, HOLD	Connect pins to VCC2 via a resistor (pull-up)
AVCC	Connect pin to VCC1
AVSS, VREF	Connect pins to VSS

NOTES:

1. If the port enters output mode and is left open, it is in input mode before output mode is entered by program after reset. While the port is in input mode, voltage level on the pins is indeterminate and power consumption may increase.
Direction register settings may be changed by noise or failure caused by noise. Configure direction register settings regularly to increase the reliability of the program.
2. Use the shortest possible wiring to connect the microcomputer pins to unassigned pins (within 2 cm).
3. P70 and P71 must outputs low-level ("L") signals if they are in output mode. They are N-channel open-drain outputs.
4. When the external clock is applied to the XIN pin, set the pin as written above.

24. Precautions

24.1 Reset

Voltage applied to the VCC1 pin must meet the SVCC standard.

Table 24.1 Power Supply Increasing Slope

Symbol	Parameter	Standard			Unit
		Min.	Typ.	Max.	
SVcc	Power Supply Increasing Slope (Vcc1)	0.05			V/ms

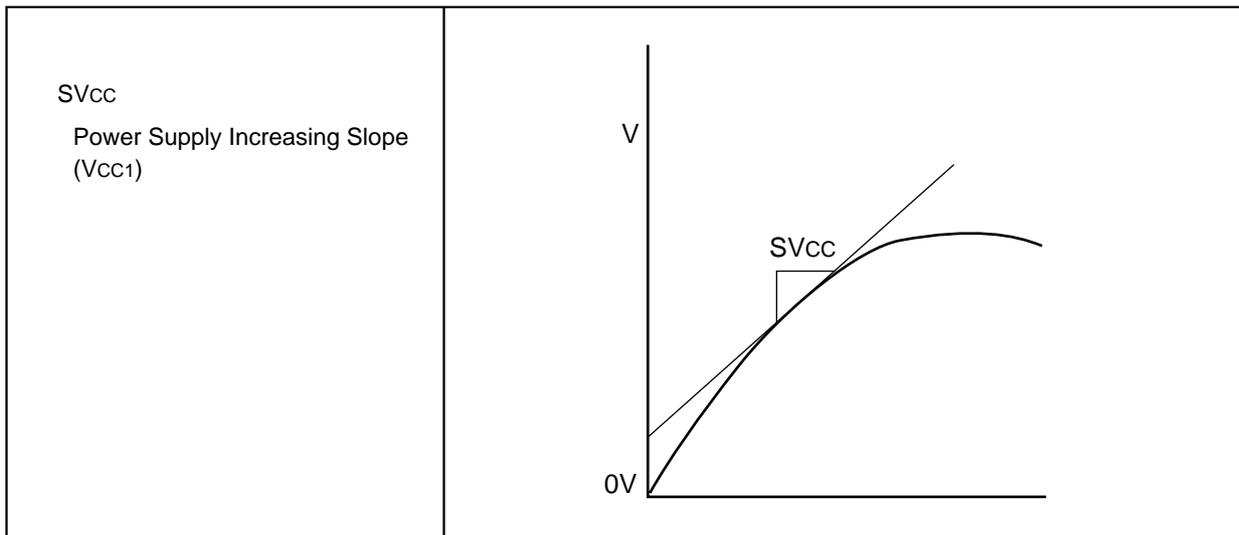

Figure 24.1 SVcc Timing

24.2 Bus

24.2.1 $\overline{\text{HOLD}}$ Signal

When entering microprocessor mode or memory expansion mode from single-chip mode and using $\overline{\text{HOLD}}$ input, set the PM01 and PM00 bits to "112" (microprocessor mode) or to "012" (memory expansion mode) after setting the PD4_7 to PD4_0 bits in the PD4 register and the PD5_2 to PD5_0 bits in the PD5 register to "0" (input mode).

P40 to P47 (A16 to A22, $\overline{\text{A23}}$, $\overline{\text{CS0}}$ to $\overline{\text{CS3}}$, MA8 to MA12) and P50 to P52 ($\overline{\text{RD/WR/BHE}}$, $\overline{\text{RD/WRL/WRH}}$) are not placed in high-impedance states even when a low-level ("L") signal is applied to the $\overline{\text{HOLD}}$ pin, if the PM01 and PM00 bits are set to "112" (microprocessor mode) or to "012" (memory expansion mode) after setting the PD4_7 to PD4_0 bits in the PD4 register and the PD5_2 to PD5_0 bits in the PD5 register to "1" (output mode) in single-chip mode.

24.3 Special Function Registers (SFRs)

24.3.1 Register Settings

Table 24.2 lists registers containing bits which can only be written to. Set these registers with immediate values. When establishing the next value by altering the present value, write the present value to the RAM as well as to the register. Transfer the next value to the register after making changes in the RAM.

Table 24.2 Registers with Write-only Bits

Register	Address	Register	Address
WDTS Register	000E ₁₆	U3BRG Register	0329 ₁₆
G0RI Register	00EC ₁₆	U3TB Register	032B ₁₆ , 032A ₁₆
G1RI Register	012C ₁₆	U2BRG Register	0339 ₁₆
U1BRG Register	02E9 ₁₆	U2TB Register	033B ₁₆ , 033A ₁₆
U1TB Register	02EB ₁₆ , 02EA ₁₆	UDF Register	0344 ₁₆
U4BRG Register	02F9 ₁₆	TA0 Register ⁽¹⁾	0347 ₁₆ , 0346 ₁₆

TA11 Register	0303 ₁₆ , 0302 ₁₆	TA2 Register ⁽¹⁾	034B ₁₆ , 034A ₁₆
TA21 Register	0305 ₁₆ , 0304 ₁₆	TA3 Register ⁽¹⁾	034D ₁₆ , 034C ₁₆
TA41 Register	0307 ₁₆ , 0306 ₁₆	TA4 Register ⁽¹⁾	034F ₁₆ , 034E ₁₆
DTT Register	030C ₁₆	U0BRG Register	0369 ₁₆
ICTB2 Register	030D ₁₆	U0TB Register	036B ₁₆ , 36A ₁₆

NOTE:

1. In one-shot timer mode and pulse width modulation mode only.

24.4 Clock Generation Circuit

24.4.1 CPU Clock

- When the CPU operating frequency is 24 MHz or more, use the following procedure for better EMC (Electromagnetic Compatibility) performance.
 - 1) Oscillator connected between the XIN and XOUT pins, or external clock applied to the XIN pin, has less than 24 MHz frequency.
 - 2) Use the PLL frequency synthesizer to multiply the main clock.

24.4.2 Sub Clock

Set the CM03 bit to "0" (XCIN-XCOUT drive capacity "LOW") when selecting the sub clock (XCIN-XCOUT) as the CPU clock, or Timer A or Timer B count source (fc32).

24.4.2.1 Sub Clock Oscillation

When oscillating the sub clock, set the CM04 bit in the CM0 register to "1" (XCIN-XCOUT oscillation function) after setting the CM07 bit in the CM0 register to "0" (clock other than sub clock) and the CM03 bit to "1" (XCIN-XCOUT drive capacity "HIGH"). Set the CM03 bit to "0" after sub clock oscillation stabilizes.

Set the sub clock as the CPU clock, or Timer A or Timer B count source (fc32) after the above settings are completed.

24.4.2.2 Using Stop Mode

When the microcomputer enters stop mode, the CM03 bit is automatically set to "1" (XCIN-XCOUT drive capacity "HIGH"). Use the following procedure to select the main clock as the CPU clock when entering stop mode.

- 1) Set the CM17 bit in the CM1 register to "0" (main clock).
- 2) Set the CM21 bit in the CM2 register to "0" (clock selected by the CM17 bit).
- 3) Set the CM07 bit in the CM0 register to "0" (clock selected by the CM21 bit divided by the MCD register setting).

After exiting stop mode, wait for the sub clock oscillation to stabilize. Then set the CM03 bit to "0" and the CM07 bit to "1" (sub clock).

24.4.2.3 Oscillation Parameter Matching

If the sub clock oscillation parameters have only been evaluated with the drive capacity "HIGH", the parameters should be reevaluated for drive capacity "LOW".

Contact your oscillator manufacturer for details on matching parameters.

24.4.3 PLL Frequency Synthesizer

Stabilize supply voltage to meet the power supply standard when using the PLL frequency synthesizer.

Table 24.3 Power Supply Ripple

Symbol	Parameter	Standard			Unit
		Min.	Typ.	Max.	
f_{ripple}	Power Supply Ripple Tolerable Frequency (V_{CC1})			10	kHz
$V_{P-P(\text{ripple})}$	Power Supply Ripple Voltage Fluctuation Range	$V_{CC1}=5V$		0.5	V
		$V_{CC1}=3.3V$		0.3	V
$V_{CC1}(\Delta V/\Delta T)$	Power Supply Ripple Voltage Fluctuation Rate	$V_{CC1}=5V$		1	V/ms
		$V_{CC1}=3.3V$		0.3	V/ms

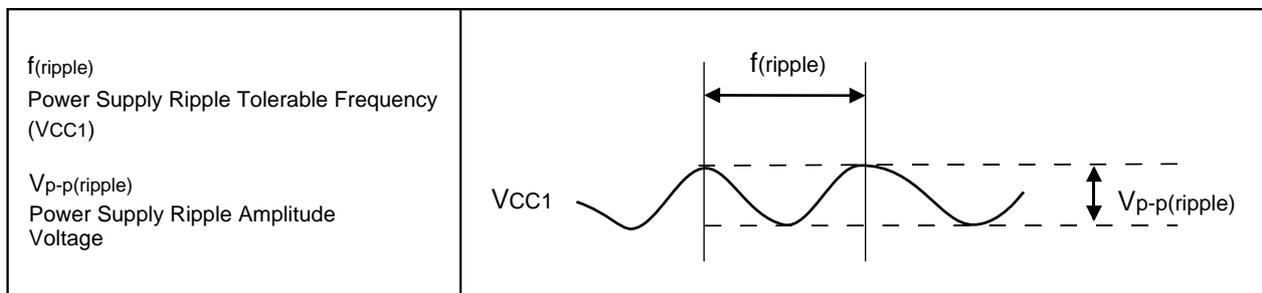

Figure 24.2 Power Supply Fluctuation Timing

24.4.4 External Clock

Do not stop an external clock running if the main clock is selected as the CPU clock while the external clock is applied to the XIN pin.

Do not set the CM05 bit in the CM0 register to "1" (main clock stopped) while the external clock input is used for the CPU clock.

24.4.5 Clock Divide Ratio

Set the PM12 bit in the PM1 register to "0" (no wait state) when changing the MCD4 to MCD0 bit settings in the MCD register.

24.4.6 Power Consumption Control

Stabilize the main clock, sub clock or PLL clock to switch the CPU clock source to each clock.

24.4.6.1 Wait Mode

When entering wait mode while the CM02 bit in the CM0 register is set to "1" (peripheral function stop in wait mode), set the MCD4 to MCD0 bits in the MCD register to maintain the 10-MHz CPU clock frequency or less.

When entering wait mode, the instruction queue reads ahead to instructions following the WAIT instruction, and the program stops. Write at least 4 NOP instructions after the WAIT instruction.

24.4.6.2 Stop Mode

- Use the following procedure to select the main clock as the CPU clock when entering stop mode.
 - 1) Set the CM17 bit in the CM1 register to "0" (main clock).
 - 2) Set the CM21 bit in the CM2 register to "0" (clock selected by the CM17 bit).
 - 3) Set the CM07 bit in the CM0 register to "0" (clock selected by the CM21 bit divided by the MCD register setting).

If the PLL clock is selected as the CPU clock source, set the CM17 bit to "0" (main clock) and the PLC07 bit in the PLC0 register to "0" (PLL off) before entering stop mode.

- The microcomputer cannot enter stop mode if a low-level signal ("L") is applied to the $\overline{\text{NMI}}$ pin. Apply a high-level ("H") signal instead.
- If stop mode is exited by any reset, apply an "L" signal to the $\overline{\text{RESET}}$ pin until a main clock oscillation is stabilized enough.
- If using the $\overline{\text{NMI}}$ interrupt to exit stop mode, use the following procedure to set the CM10 bit in the CM1 register (all clocks stopped).
 - 1) Exit stop mode with using the $\overline{\text{NMI}}$ interrupt.
 - 2) Generate a dummy interrupt.
 - 3) Set the CM10 bit to "1".

```
e.g.,      int   #63                ; dummy interrupt
           bset  cm1                ; all clocks stopped
```

```
/* dummy interrupt handling */
```

```
dummy
  reit
```

- When entering stop mode, the instruction queue reads ahead to instructions following the instruction setting the CM10 bit in the CM1 register to "1" (all clocks stopped), and the program stops. When the microcomputer exits stop mode, the instruction lined in the instruction queue is executed before the interrupt routine for recovery is done.

Write the JMP.B instruction, as follows, after the instruction setting the CM10 bit in the CM1 register to "1" (all clocks stopped).

```
e.g.,      bset 0, prcr              ; protection removed
           bset 0, cm1              ; all clocks stopped
           jmp.b LABEL_001         ; JMP.B instruction executed (no instuction between JMP.B
                                   ; and LABEL.)
```

```
LABEL_001:
  nop                ; NOP (1)
  nop                ; NOP (2)
  nop                ; NOP (3)
  nop                ; NOP (4)
  mov.b #0, prcr     ; Protection set
  .
  .
  .
```

24.4.6.3 Suggestions for Reducing Power Consumption

The followings are suggestions for reducing power consumption when programming or designing systems.

Ports: I/O ports maintains the same state despite the microcomputer entering wait mode or stop mode. Current flows through active output ports. Feedthrough current flows through input ports in a high-impedance state. Set unassigned ports as input ports and stabilize electrical potential before entering wait mode or stop mode.

A/D Converter: If the A/D conversion is not performed, set the VCUT bit in the AD0CON1 register to "0" (no VREF connection). Set the VCUT bit to "1" (VREF connection) and wait at least 1 μ s before starting the A/D conversion.

D/A Converter: Set the DAi bit (i=0, 1) in the DACON register to "0" (output disabled) and set the DAi register to "00₁₆" when the D/A conversion is not performed.

Peripheral Function Stop: Set the CM02 bit in the CM0 register while in wait mode to stop unnecessary peripheral functions. However, this does not reduce power consumption because the peripheral function clock (fc32) generating from the sub clock does not stop. When in low-speed mode and low-power consumption mode, do not enter wait mode when the CM02 bit is set to "1" (peripheral clock stops in wait mode).

24.5 Protection

The PRC2 bit setting in the PRCR register is changed to "0" (write disabled) when an instruction is written to any address after the PRC2 bit is set to "1" (write enabled). Write instruction immediately after setting the PRC2 bit to "1" to change registers protected by the PRC2 bit. Do not generate an interrupt or a DMA transfer between the instruction to set the PRC2 bit to "1" and the following instruction.

24.6 Interrupts

24.6.1 ISP Setting

After reset, the ISP is set to "00000016". The program runs out of control if an interrupt is acknowledged before the ISP is set. Therefore, the ISP must be set before an interrupt request is generated. Set the ISP to an even address, which allows interrupt sequences to be executed at a higher speed.

To use $\overline{\text{NMI}}$ interrupt, set the ISP at the beginning of the program. The $\overline{\text{NMI}}$ interrupt can be acknowledged after the first instruction has been executed after reset.

24.6.2 $\overline{\text{NMI}}$ Interrupt

- $\overline{\text{NMI}}$ interrupt cannot be denied. Connect the $\overline{\text{NMI}}$ pin to Vcc via a resistor (pull-up) when not in use.
- The P8_5 bit in the P8 register indicates the $\overline{\text{NMI}}$ pin value. Read the P8_5 bit only to determine the pin level after a $\overline{\text{NMI}}$ interrupt occurs.
- "H" and "L" signals applied to the $\overline{\text{NMI}}$ pin must be over 2 CPU clock cycles + 300 ns wide.
- $\overline{\text{NMI}}$ interrupt request may not be acknowledged if this and other interrupt requests are generated simultaneously.

24.6.3 $\overline{\text{INT}}$ Interrupt

- Edge Sensitive
"H" and "L" signals applied to the $\overline{\text{INT0}}$ to $\overline{\text{INT5}}$ pins must be at least 250 ns wide, regardless of the CPU clock.
- Level Sensitive
"H" and "L" signals applied to the $\overline{\text{INT0}}$ to $\overline{\text{INT5}}$ pins must be at least 1 CPU clock cycle + 200 ns wide. For example, "H" and "L" must be at least 234ns wide if $X_{IN}=30\text{MHz}$ with no division.
- The IR bit setting may change to "1" (interrupt requested) when switching the polarity of the $\overline{\text{INT0}}$ to $\overline{\text{INT5}}$ pins. Set the IR bit to "0" (no interrupt requested) after selecting the polarity. Figure 24.3 shows an example of the switching procedure for the $\overline{\text{INT}}$ interrupt.

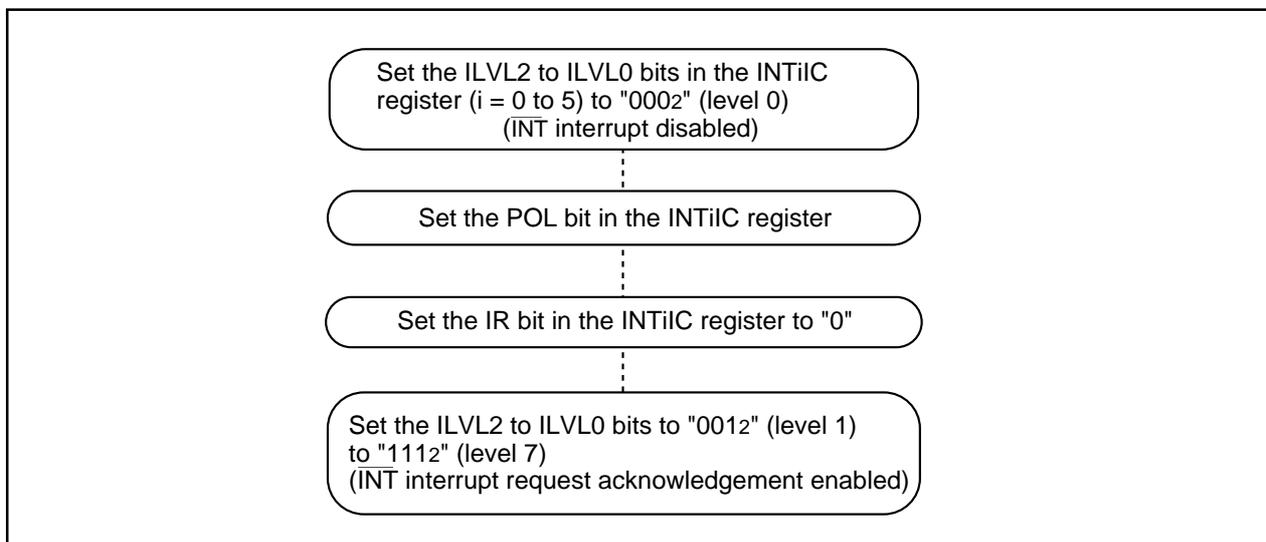

Figure 24.3 Switching Procedure for $\overline{\text{INT}}$ Interrupt

24.6.4 Watchdog Timer Interrupt

Reset the watchdog timer after a watchdog timer interrupt occurs.

24.6.5 Changing Interrupt Control Register

To change the interrupt control register while the interrupt request is denied, follow the instructions below.

Changing IR bit

The IR bit setting may not change to "0" (no interrupt requested) depending on the instructions written. If this is a problem, use the following instruction to change the register: MOV

Changing Bits Except IR Bit

When an interrupt request is generated while executing an instruction, the IR bit may not be set to "1" (interrupt requested) and the interrupt may be ignored. If this is a problem, use the following instructions to change the register: AND, OR, BCLR, BSET

24.6.6 Changing IIOiR Register (i = 0 to 4)

Use the following instructions to set bits 1 to 7 in the IIOiR register to "0" (no interrupt requested): AND, BCLR

24.6.7 Changing RLVL Register

The DMAII bit is indeterminate after reset. When using the DMAII bit to generate an interrupt, set the interrupt control register after setting the DMAII bit to "0" (interrupt priority level 7 available for interrupts).

24.7 DMAC

- Set DMAC-associated registers while the MDi1 and MDi0 bits (i=0 to 3) in the channel to be used are set to "002" (DMA disabled). Set the MDi1 and MDi0 bits to "012" (single transfer) or "112" (repeat transfer) at the end of setup procedure to start DMA requests.
- Do not set the DRQ bit in the DMiSL register to "0" (no request).
If a DMA request is generated but the receiving channel is not ready to receive⁽¹⁾, the DMA transfer does not occur and the DRQ bit is set to "0".

NOTE:

1. The MDi1 and MDi0 bits are set to "002" or the DCTi register is set to "0000₁₆" (transferred 0 times).
- To start a DMA transfer by a software trigger, set the DSR bit and DRQ bit in the DMiSL register to "1" simultaneously.
e.g.,

```
OR.B #0A0h,DMiSL ; Set the DSR and DRQ bits to "1" simultaneously
```
 - Do not generate a channel i DMA request when setting the MDi1 and MDi0 bits in the DMDj register (j=0,1) corresponding to channel i to "012" (single transfer) or "112" (repeat transfer), if the DCTi register of channel i is set to "1".
 - Select the peripheral function which causes the DMA request after setting the DMA-associated registers. If none of the conditions above (setting $\overline{\text{INT}}$ interrupt as DMA request source) apply, do not write "1" to the DCTi register.
 - Enable DMA⁽²⁾ after setting the DMiSL register (i=0 to 3) and waiting six BCLK cycles or more by program.

NOTE:

2. DMA is enabled when the values set in the MDi1 and MDi0 bits in the DMDj register are changed from "002" (DMA disabled) to "012" (single transfer) or "112" (repeat transfer).

24.8 Timer

24.8.1 Timers A and B

Timers stop after reset. Set the TAI_S(i=0 to 4) bit or TB_jS(j=0 to 5) bit in the TABSR register or TBSR register to "1" (starts counting) after setting operating mode, count source and counter.

The following registers and bits must be set while the TAI_S bit or TB_jS bit is set to "0" (stops counting).

- TAI_MR, TB_jM_R register
- TAI, TB_j register
- UDF register
- TAZIE, TA0TGL, TA0TGH bits in the ONSF register
- TRGSR register

24.8.2 Timer A

The TA1_{OUT}, TA2_{OUT} and TA4_{OUT} pins are placed in high-impedance states when a low-level ("L") signal is applied to the $\overline{\text{NMI}}$ pin while the INV03 and INV02 bits in the INVC0 register are set to "112" (forced cutoff of the three-phase output by an "L" signal applied to the $\overline{\text{NMI}}$ pin).

24.8.2.1 Timer A (Timer Mode)

- The TAI_S bit (i=0 to 4) in the TABSR register is set to "0" (stops counting) after reset. Set the TAI_S bit to "1" (starts counting) after selecting an operating mode and setting the TAI register.
- The TAI register indicates the counter value during counting at any given time. However, the counter is "FFFF₁₆" when reloading. The setting value can be read after setting the TAI register while the counter stops and before the counter starts counting.

24.8.2.2 Timer A (Event Counter Mode)

- The TAI_S (i=0 to 4) bit in the TABSR register is set to "0" (stops counting) after reset. Set the TAI_S bit to "1" (starts counting) after selecting an operating mode and setting the TAI register.
- The TAI register indicates the counter values during counting at any given time. However, the counter will be "FFFF₁₆" during underflow and "0000₁₆" during overflow, when reloading. The setting value can be read after setting the TAI register while the counter stops and before the counter starts counting.

24.8.2.3 Timer A (One-shot Timer Mode)

- The TAI_S (i=0 to 4) bit in the TABSR register is set to "0" (stops counting) after reset. Set the TAI_S bit to "1" (starts counting) after selecting an operating mode and setting the TAI register.
- The followings occur when the TABSR register is set to "0" (stops counting) while counting:
 - The counter stops counting and the microcomputer reloads contents of the reload register.
 - The TAI_{OUT} pin becomes low ("L").
 - The IR bit in the TAI_{IC} register is set to "1" (interrupt requested) after one CPU clock cycle.
- The output of the one-shot timer is synchronized with an internal count source. When set to an external trigger, there is a delay of one count source cycle maximum, from trigger input to the TAI_{IN} pin to the one-shot timer output.
- The IR bit is set to "1" when the following procedures are performed to set timer mode:
 - selecting one-shot timer mode after reset.
 - switching from timer mode to one-shot timer mode.
 - switching from event counter mode to one-shot timer mode.
 Therefore, set the IR bit to "0" to generate a timer A_i interrupt (IR bit) after performing these procedures.
- When a trigger is generated while counting, the reload register reloads and continues counting after the counter has decremented once following a re-trigger. To generate a trigger while counting, wait at least 1 count source cycle after the previous trigger has been generated and generate a re-trigger.
- If an external trigger input is selected to start counting in timer A one-shot timer mode, do not provide another external trigger input again for 300 ns before the timer A counter value reaches "0000₁₆". One-shot timer may stop counting.

24.8.2.4 Timer A (Pulse Width Modulation Mode)

- The TAI_S(i=0 to 4) bit in the TABSR register is set to "0" (stops counting) after reset. Set the TAI_S bit to "1" (starts counting) after selecting an operating mode and setting the TAI register.
- The IR bit is set to "1" when the following procedures are performed to set timer mode:
 - Selecting PWM mode after reset
 - Switching from timer mode to PWM mode
 - Switching from event counter mode to PWM mode
 Therefore, set the IR bit to "0" by program to generate a timer A_i interrupt (IR bit) after performing these procedures.
- The followings occur when the TAI_S bit is set to "0" (stops counting) while PWM pulse is output:
 - The counter stops counting
 - Output level changes to low ("L") and the IR bit changes to "1" when the TAI_{OUT} pin is held high ("H")
 - The IR bit and the output level remain unchanged when TAI_{OUT} pin is held "L"

24.8.3 Timer B

24.8.3.1 Timer B (Timer Mode, Event Counter Mode)

- The TBiS (i=0 to 5) bit is set to "0" (stops counting) after reset. Set the TBiS bit to "1" (starts counting) after selecting an operating mode and setting TBi register.
The TB2S to TB0S bits are bits 7 to 5 in the TABSR register. The TB5S to TB3S bits are bits 7 to 5 in the TBSR register.
- The TBi register indicates the counter value during counting at any given time. However, the counter is "FFFF16" when reloading. The setting value can be read after setting the TBi register while the counter stops and before the counter starts counting.

24.8.3.2 Timer B (Pulse Period/Pulse Width Measurement Mode)

- The IR bit in the TBiIC (i=0 to 5) register is set to "1" (interrupt requested) when the valid edge of a pulse to be measured is input and when the timer Bi counter overflows. The MR3 bit in the TBiMR register determines the interrupt source within an interrupt routine.
- Use another timer to count how often the timer counter overflows when an interrupt source cannot be determined by the MR3 bit, such as when a pulse to be measured is input at the same time the timer counter overflows.
- To set the MR3 bit in the TBiMR register to "0" (no overflow), set the TBiMR register after the MR3 bit is set to "1" (overflow) and one or more cycles of the count source are counted, while the TBiS bits in the TABSR and TBSR registers are set to "1" (starts counting).
- The IR bit in the TBiIC register is used to detect overflow only. Use the MR3 bit only to determine interrupt source within an interrupt routine.
- Indeterminate values are transferred to the reload register during the first valid edge input after counting is started. Timer Bi interrupt request is not generated at this time.
- The counter value is indeterminate when counting is started. Therefore, the MR3 bit setting may change to "1" (overflow) and causes timer Bi interrupt requests to be generated until a valid edge is input after counting is started.
- The IR bit may be set to "1" (interrupt requested) if the MR1 and MR0 bits in the TBiMR register are set to a different value after a count begins. If the MR1 and MR0 bits are rewritten, but to the same value as before, the IR bit remains unchanged.
- Pulse width measurement measures pulse width continuously. Use program to determine whether measurement results are high ("H") or low ("L").

24.9 Serial I/O

24.9.1 Clock Synchronous Serial I/O Mode

The $\overline{\text{RTS}}_2$ and CLK_2 pins are placed in high-impedance states when a low-level ("L") signal is applied to the $\overline{\text{NMI}}$ pin while the INV03 and INV02 bits in the INVC0 register are set to "112" (forced cutoff of the three-phase output by an "L" signal applied to the $\overline{\text{NMI}}$ pin).

24.9.1.1 Transmission /Reception

When the $\overline{\text{RTS}}$ function is used while an external clock is selected, the output level of the $\overline{\text{RTS}}_i$ pin is held "L" indicating that the microcomputer is ready for reception. The transmitting microcomputer is notified that reception is possible. The output level of the $\overline{\text{RTS}}_i$ pin becomes high ("H") when reception begins. Therefore, connecting the $\overline{\text{RTS}}_i$ pin to the $\overline{\text{CTS}}_i$ pin of the transmitting microcomputer synchronizes transmission and reception. The $\overline{\text{RTS}}$ function is disabled if an internal clock is selected.

24.9.1.2 Transmission

When an external clock is selected while the CKPOL bit in the UiC0 ($i=0$ to 4) register is set to "0" (data is transmitted on the falling edge of the transfer clock and received on the rising edge) and the external clock is held "H", or when the CKPOL bit is set to "1" (data is transmitted on the rising edge of the transfer clock and received on the falling edge) and the external clock is held "L", meet the following conditions:

- Set the TE bit in the UiC1 register to "1" (receive enabled)
- Set the TI bit in the UiC1 register to "0" (data in the UiTB register)
- Apply "L" signal to the $\overline{\text{CTS}}_i$ pin if the $\overline{\text{CTS}}$ function is selected

24.9.1.3 Reception

Activating the transmitter in clock synchronous serial I/O mode generates the shift clock. Therefore, set for transmission even if the microcomputer is used for reception only. Dummy data is output from the TxDi pin while receiving.

If an internal clock is selected, the shift clock is generated when the TE bit in the UiC1 registers is set to "1" (receive enabled) and dummy data is set in the UiTB register. If an external clock is selected, the shift clock is generated when the external clock is input into CLK_i pin while the TE bit is set to "1" (receive enabled) and dummy data is set in the UiTB register.

When receiving data consecutively while the RE bit in the UiC1 register is set to "1" (data in the UiRB register) and the next data is received by the UART_i reception register, an overrun error occurs and the OER bit in the UiRB register is set to "1" (overrun error). In this case, the UiRB register is indeterminate. When overrun error occurs, program both reception and transmission registers to retransmit earlier data. The IR bit in the SiRIC does not change when an overrun error occurs.

When receiving data consecutively, feed dummy data to the low-order byte in the UiTB register every time a reception is made.

When an external clock is selected while the CKPOL bit in the UiC0 register is set to "0" (data is transmitted on the falling edge of the transfer clock and received on the rising edge) and the external clock is held "H" or when the CKPOL bit is set to "1" (data is transmitted on the rising edge of the transfer clock and received on the falling edge) and the external clock is held "L", meet the following conditions:

- Set the RE bit in the UiC1 register to "1" (receive enabled)
- Set the TE bit in the UiC1 register to "1" (transmit enabled)
- Set the TI bit in the UiC1 register to "0" (data in the UiTB register)

24.9.2 UART Mode

Set the UiERE bit (i=0 to 4) in the UiC1 register after setting the UiMR register.

24.9.3 Special Mode 1 (I²C Mode)

To generate the start condition, stop condition or restart condition, set the STSPSEL bit in the UiSMR4 register to "0" first. Then, change each condition generating bit (the STAREQ bit, STPREQ bit or RSTAREQ bit) setting from "0" to "1" after going through a half cycle of the transfer clock.

24.10 A/D Converter

- Set the AD0CON0 (bit 6 excluded), AD0CON1, AD0CON2, AD0CON3, and AD0CON4 registers while the A/D conversion is stopped (before a register is generated).
- Wait a minimum of 1 μ s before starting the A/D conversion when changing the VCUT bit setting in the AD0CON1 register from "0" (VREF no connection) to "1" (VREF connection). Change the VCUT bit setting from "1" to "0" after the A/D conversion is completed.
- Insert capacitors between the AVCC pin, VREF pin, analog input pin ANi (i=0 to 7) and AVSS pin to prevent latch-ups and malfunctions due to noise, and to minimize conversion errors. The same applies to the VCC and VSS pins. Figure 24.4 shows the use of capacitors to reduce noise.

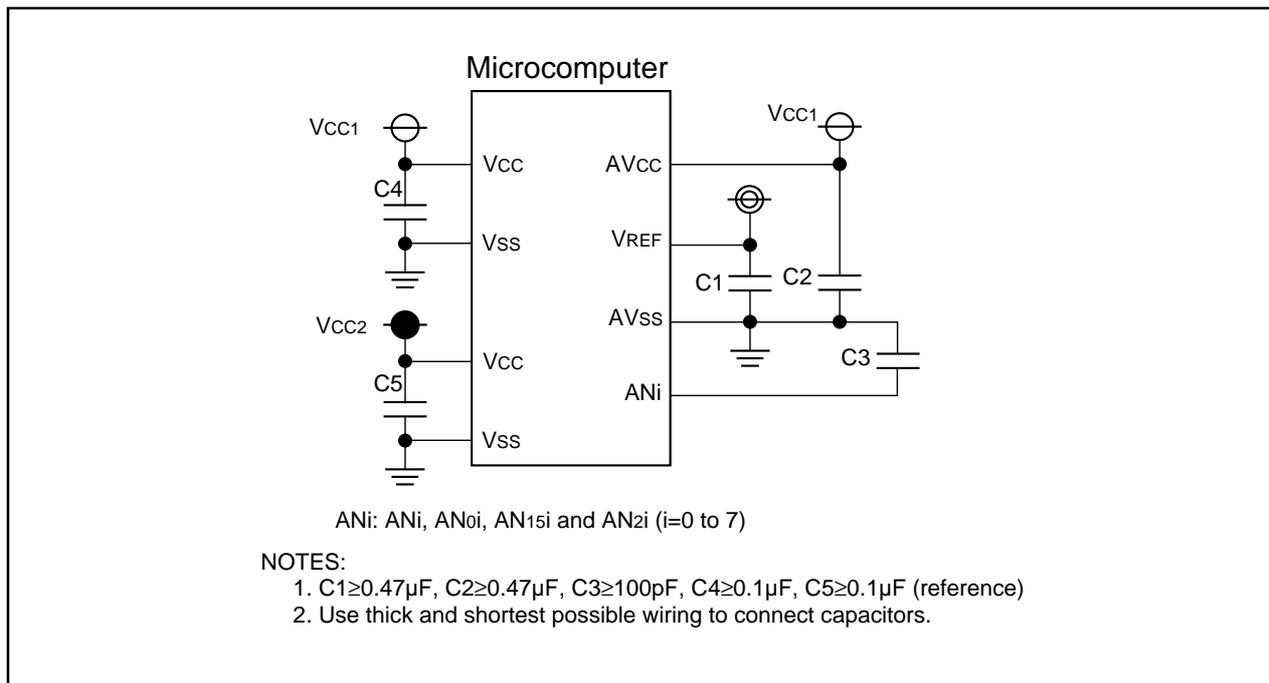

Figure 24.4 Use of Capacitors to Reduce Noise

- Set the bit in the port direction register, which corresponds to the pin being used as the analog input, to "0" (input mode). Set the bit in the port direction register, which corresponds to the \overline{ADTRG} pin, to "0" (input mode) if the TRG bit in the AD0CON0 register is set to "1" (external trigger).
- When generating a key input interrupt, do not use the AN4 to AN7 pins as analog input pins (key input interrupt request is generated when the A/D input voltage becomes "L").
- The ϕ_{AD} frequency must be 16MHz or less. When the sample and hold function is not activated, the ϕ_{AD} frequency must be 250 kHz or more. If the sample and hold function is activated, the ϕ_{AD} frequency must be 1MHz or more.
- Set the CH2 to CH0 bits in the AD0CON0 register or the SCAN1 and SCAN0 bits in the AD0CON1 register to re-select analog input pins when changing A/D conversion mode.

- $AVCC = VREF = VCC1$, A/D input voltage (for AN0 to AN7, ANEX0, and ANEX1) $\leq VCC1$.
- Wrong values are stored in the AD0i register (i=0 to 7) if the CPU reads the AD0i register while the AD0i register stores results from a completed A/D conversion. This occurs when the CPU clock is set to a divided main clock or a sub clock.
In one-shot mode or single sweep mode, read the corresponding AD0i register after verifying that the A/D conversion has been completed. The IR bit in the AD0IC register determines the completion of the A/D conversion.
In repeat mode, repeat sweep mode 0 and repeat sweep mode 1 use an undivided main clock as the CPU clock.
- Conversion results of the A/D converter are indeterminate if the ADST bit in the AD0CON0 register is set to "0" (A/D conversion stopped) and the conversion is forcibly terminated by program during the A/D conversion. The AD0i register not performing the A/D conversion may also be indeterminate.
If the ADST bit is changed to "0" by program, during the A/D conversion, do not use any values obtained from the AD0i registers.
- External triggers cannot be used in DMAC operating mode. Do not read the AD00 register by program.
- Do not perform the A/D conversion in wait mode.
- Set the MCD4 to MCD0 bits in the MCD register to "100102" (no division) if using the sample and hold function.
- Do not acknowledge any interrupt requests, even if generated, before setting the ADST bit, if the A/D conversion is terminated by setting the ADST bit in the AD0CON0 register to "0" (A/D conversion stopped) while the microcomputer is A/D converting in single sweep mode.

24.11 Intelligent I/O

24.11.1 Register Setting

Operations, controlled by the values written to the G0RI and G1RI, G0TO and G1TO, G0CR and G1CR, G0RB and G1RB, G0MR and G1MR, G0EMR and G1EMR, G0ETC and G1ETC, G0ERC and G1ERC, G0IRF, G1IRF, G0TB and G1TB, G0CMP0 to G0CMP3, G1CMP0 to G1CMP3, G0MSK0 and G0MSK1, G1MSK0 and G1MSK1, G0TCRC and G1TCRC, G0RCRC and G1RCRC registers are affected by the transfer clock.

Set transfer clock before setting the G0RI and G1RI, G0TO and G1TO, G0CR and G1CR, G0RB and G1RB, G0MR and G1MR, G0EMR and G1EMR, G0ETC and G1ETC, G0ERC and G1ERC, G0IRF and G1IRF, G0TB and G1TB, G0CMP0 to G0CMP3, G1CMP0 to G1CMP3, G0MSK0 and G0MSK1, G1MSK0 and G1MSK1, G0TCRC and G1TCRC, G0RCRC and G1RCRC registers.

24.12 Programmable I/O Ports

- Because ports P72 to P75, P80, and P81 have three-phase PWM output forced cutoff function, they are affected by the three-phase motor control timer function and the $\overline{\text{NMI}}$ pin when these ports are set for output functions (port output, timer output, three-phase PWM output, serial I/O output, intelligent I/O output).

Table 24.4 shows the INVC0 register setting, the $\overline{\text{NMI}}$ pin input level and the state of output ports.

Table 24.4 INVC0 Register and the $\overline{\text{NMI}}$ Pin

Setting Value of the INVC0 Register		Signal level Applied to the $\overline{\text{NMI}}$ Pin	P72 to P75, P80, P81 Pin States (When Setting Them as Output Pins)
INV02 Bit	INV03 Bit		
0 (Not Using the Three-Phase Motor Control Timer Functions)	-	-	Provides functions selected by the PS1, PSL1, PSC, PS2, PSL2 registers
1 (Using the Three-Phase Motor Control Timer Functions)	0 (Three-Phase Motor Control Timer Output Disabled)	-	High-impedance state
	1 (Three-Phase Motor Control Timer Output Enabled) ⁽¹⁾	H	Provides functions selected by the PS1, PSL1, PSC, PS2, PSL2 registers
		L (Forcibly Terminated)	High-impedance state

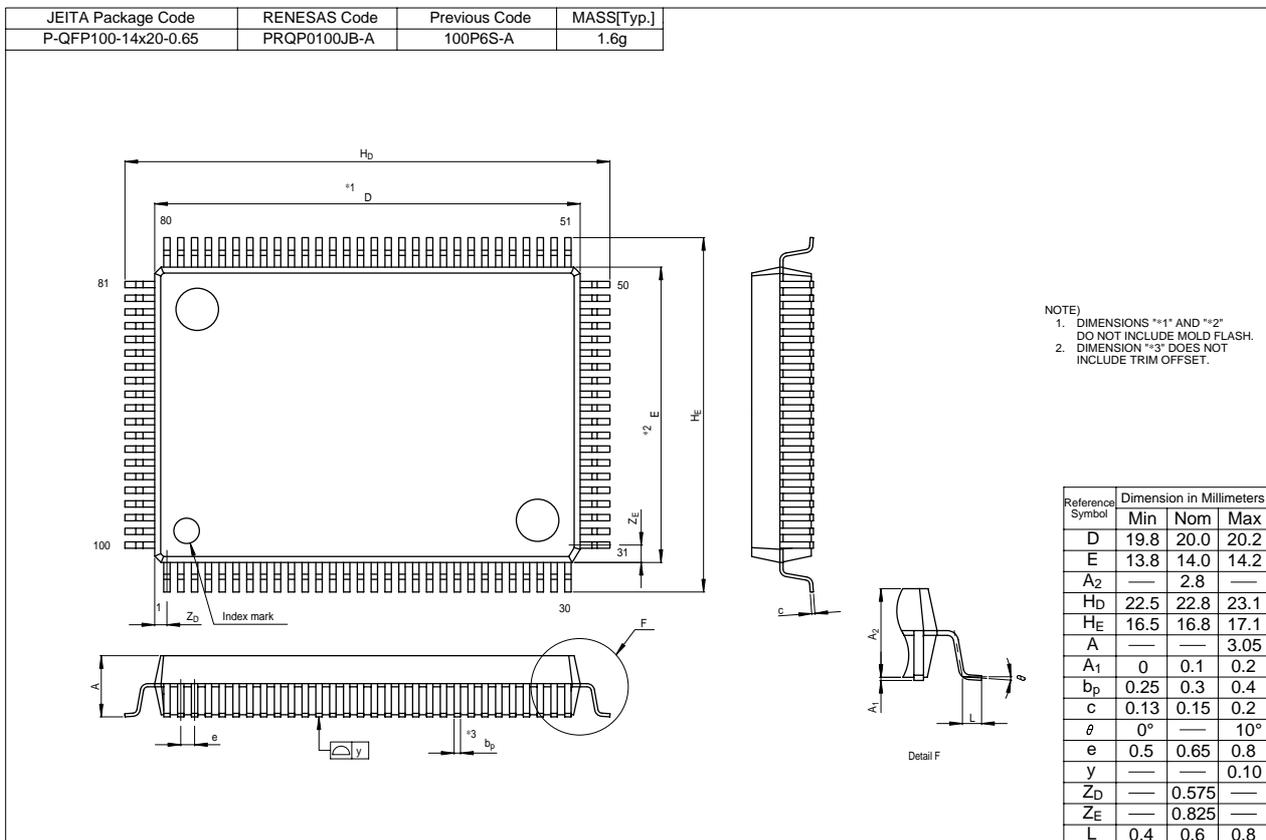

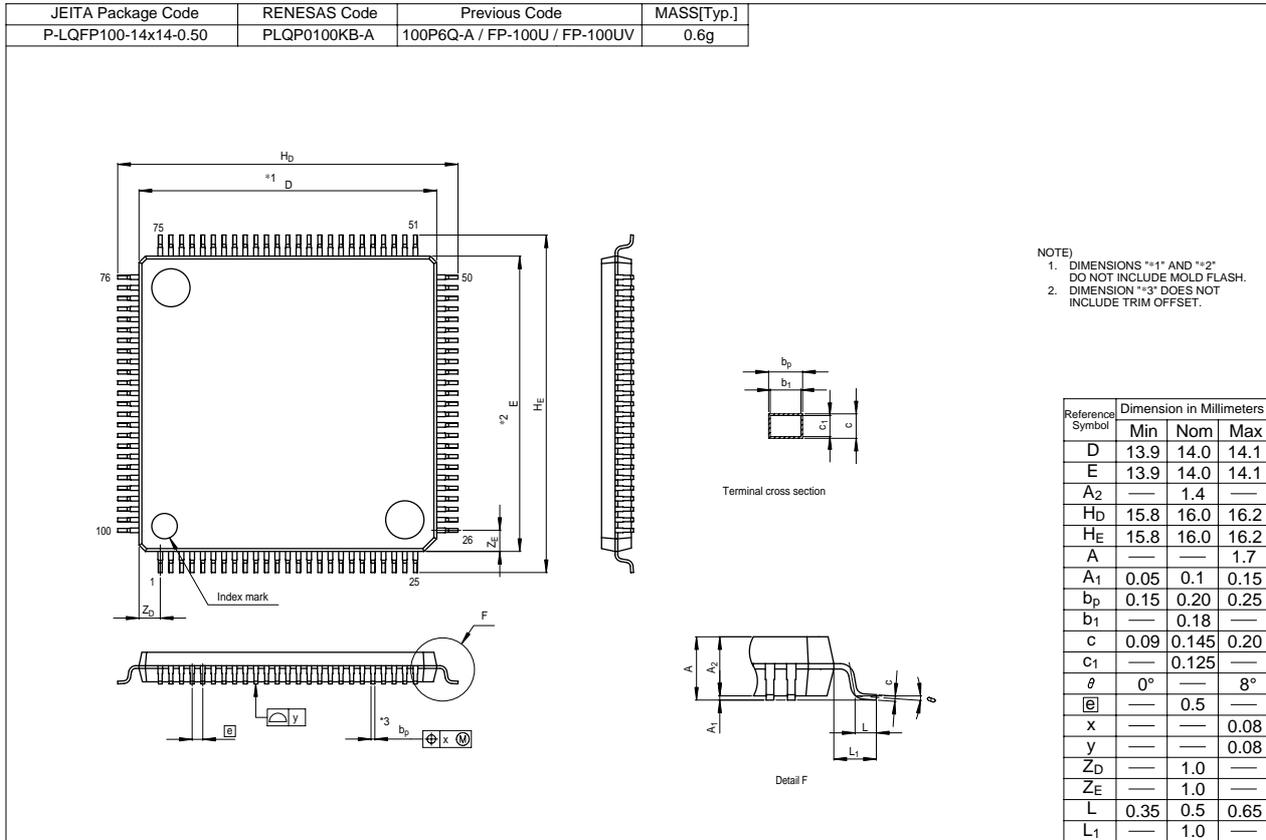

NOTE:

1. The INV03 bit is set to "0" after a low-level ("L") signal is applied to the $\overline{\text{NMI}}$ pin.
- The availability of pull-up resistors is indeterminate until internal power voltage stabilizes, if the RESET pin is held "L".
 - The input threshold voltage varies between programmable I/O ports and peripheral functions. Therefore, if the level of the voltage applied to a pin shared by both programmable I/O ports and peripheral functions is not within the recommended operating condition, V_{IH} and V_{IL} (neither "H" nor "L"), the level may vary depending on the programmable ports and peripheral functions.

24.13 Noise

Connect a bypass capacitor (0.1 μ F or more) between Vcc and Vss by shortest path, using thick wires.
